13. ABSTRACT (Maximum 200 Words) We have made extensive progress to support our analysis of the BAP1-BRCA1 interaction. We have published the co-localization and cell-cycle patterns of intranuclear distribution for the two proteins. In addition, we have shown that BAP-1 is a bonafide tumor suppressor gene which is able to inhibit the malignant growth characteristics of cell lines when transfected back into the BAP1 null cells. This activity is dependent upon enzymatic function of the ubiquitin hydrolysis domain. Our recent studies are aimed at exploring whether BAP1, like BRCA1, might have a direct role in transcription-coupled DNA repair. The work accomplished conforms to the original SOW and has shed new light on the role of BRCA1 as a tumor suppressor in early onset familial breast-ovarian cancer families

Introduction:

The search for the functions of BRCA1 have suggested a global role in nuclear processes involving transcriptional regulation, DNA repair and recombination. However, less clear is the mechanism by which these activities of BRCA1 are coordinated at the cellular level. A fruitful strategy has been to identify BRCA1 binding proteins and determine their roles in this regulatory hierarchy. We have identified a novel protein, BAP1 (BRCA1 Associated Protein-1), which binds to the wild-type, but not to a mutated, BRCA1 RING finger domain (1). BAP1 is a novel, nuclear-localized member of the ubiquitin carboxy-terminal hydrolase (UCH) family of enzymes (reviewed in (2, 3)). BAP1 is a 729 a.a. protein (90 kDa apparent molecular weight) that binds to BRCA1 *in vitro* and *in vivo*, cleaves ubiquitin from a model substrate, is co-expressed temporally and spatially with BRCA1, and enhances the growth suppressive properties of BRCA1.

Via its association with BRCA1, BAP1 is indirectly implicated in a linkage between DNA repair processes and ubiquitin metabolism. A substantial body of evidence points to a function for BRCA1 as a scaffold for assembly of different effector complexes of DNA repair including components of mechanisms for homologous recombination (HR), mismatch repair (MMR), nucleotide excision repair (NER), and Transcription-Coupled Repair (4-12). BRCA1 can also associate with proteins such as p53 (13), BRCA2 (14, 15), and the RAD51/52 complex (16) that serve a role in DNA repair. Furthermore these BRCA1-associated proteins are either regulated through the ubiquitin/proteasome pathway (7) or associate with ubiquitin-like proteins, e.g. UBL-1 (17, 18) and a ubiquitin-like conjugating enzyme, hUBC9/UBE2I (19). Moreover, the recent discoveries that many RING finger proteins, including BRCA1 can function as ubiquitin E3 ligases further underscores the converging functions of DNA repair and ubiquitin metabolism (20-22). Thus, the BRCA1/BRCA2-RAD51 DNA repair complex potentially contains the elements necessary to conjugate a ubiquitin-like molecule, and may also have capacity for ubiquitin removal, via the associated BAP1-mediated ubiquitin hydrolysis. Our current focus is the definition of the substrates for BAP1 enzymatic activity and to determine mechanistically how it might work together with BRCA1 in DNA repair. BAP1's potential importance in genomic stability and integrity is signaled by the mapping of the human *BAP1* locus to chromosome 3p21.3 (1), a region of the genome that is routinely deleted or rearranged in many cancers. We have found rearrangements, deletions and missense mutations of *BAP1* in small cell and non-small cell lung cancer cell lines and, more recently, in breast cancer tumor samples. These data suggest that *BAP1* may be a tumor suppressor gene. In this last period of support we have investigated this possibility by transfecting BAP1 or enzymatically inactive forms of BAP1 into the non-small cell lung cancer cell line NCI-H226, a cell line lacking endogenous BAP1 (1). Our results show that wild-type BAP1 decreases cell growth, changes cell shape and inhibits *in vivo* tumor growth. We are currently using stable H226 cell lines complemented with wild type, or mutant BAP1 cDNAs to explore the role of BAP1 in BRCA1-mediated DNA repair processes. In the original proposal we aimed to:

Specific Aim 1. Characterize the interaction of BRCA1 and S6 kinase,

Specific Aim 2. Characterize the BRCA1-associated protein BAP-1,

Specific Aim 3. Characterize BAP-1/BRCA1 in primary breast cancer specimens, look for mutations in the BAP-1 gene, and determine if expression of BAP1 in breast cancer cells influences BRCA1 function..

Body

Specific Aim 1: Characterize the interaction of BRCA1 Ring Finger and S6 kinase.

One of the original BRCA1-interacting clones from the two hybrid analysis was the kinase p70/85S6k (S6 kinase), which phosphorylates the 40S ribosomal protein S6. Using a biochemical co-immunoprecipitation approach, we were unable to confirm the interaction of these proteins *in vitro*. Because this interaction could not be confirmed biochemically we did not address whether the BRCA1 RING-finger is a substrate for this kinase or whether the RING-finger can modulate the activity of S6 kinase (tasks 2-4). Instead we focused our efforts towards characterizing the intracellular pattern of BRCA1 expression in the nucleus and described dynamic redistribution of expression patterns during viral infection and during the cell cycle. These findings were published in reference (23), (see Appendices). We also successfully established vectors for production and purification of wild-type and mutant BRCA1-Ring Finger proteins and used these proteins to develop and characterize the BR64 monoclonal antibody to BRCA1 (task 5) (23).

Specific Aim 2: Characterize the BRCA1 associated protein BAP-1.

The major emphasis has been placed in the characterization of the BRCA1 associated protein BAP-1 and the findings have been published in reference (1), (see Appendices). This manuscript details the discovery and characterization of a novel protein, BAP1, which binds to the BRCA1 RING finger motif. The full length BAP1 cDNA clones were successfully isolated and sequenced (tasks 6 and 7). The isolation of genomic clones of BAP1 and analysis of the intron/exon organization of genomic BAP1 has been completed and is currently in preparation for publication. We have also successfully prepared recombinant peptides of purified BAP1 and used these to generate highly specific monoclonal (manuscript in preparation), and polyclonal (1, 13) antibodies (tasks 8 and 9). We have applied these antibodies to coimmunoprecipitate BRCA1 and BAP1 from cell lysates (1) and to demonstrate partial nuclear co-localization (23). Although our attempts at demonstrating a direct interaction between BRCA1 and BAP1 recombinant peptides produced and purified from bacteria have not been successful, we have initiated a collaboration with Prof. Rachel E. Klevit of the University of Washington who has recently informed us of results showing that the BAP1 forms a heterodimeric complex with the N-terminal domain of BRCA1, (hence, task 10 is successfully completed).

BAP1 is the newest member of the ubiquitin C-terminal hydrolase (UCH) family of proteins and considerably expands the potential roles of this family of proteases. BAP1 is a much larger protein (90 kDa) and is the first nuclear-localized UCH. In addition to containing the ~250 amino acid amino-terminal UCH catalytic domain, it includes a long carboxy-terminal extension with rich in proline, serine and threonine and a short, highly acidic region, elements which may confer a short half-life. The extreme carboxy-terminus encodes two potential nuclear localization signals that overlap the approximately 125 amino acid BRCA1 interaction domain. It was this domain that was independently isolated from mouse and human libraries in the two-hybrid screen and is predicted to fold into a long amphipathic helix of coiled-coil character, the structure of which may be important for BRCA1 interaction: Substitution of proline 691 with a leucine abolishes the BAP1-BRCA1 interaction. Thus we have successfully accomplished task 11 which was to prepare mutations/deletions of BRCA1 and BAP1 to map the interaction

domains (1). We have also detected a potential splice variant in BAP1 which results in loss of 31 amino acids of the BRCA1 interaction domain and greatly reduces the ability of BAP1 to bind the BRCA1 RING finger, further suggesting that the BAP1-BRCA1 interaction is regulated. Thus, our data suggest that the BAP1 carboxy-terminus is tethered to BRCA1 via the RING finger domain and that the UCH catalytic domain is free to interact with ubiquitin substrates.

Specific Aim 3. Characterize BAP-1/BRCA1 in primary breast cancer specimens, look for mutations in the BAP-1 gene, and determine if expression of BAP1 in breast cancer cells influences BRCA1 function.

In our previous report we had suggested that BAP1 may have growth/tumor suppressive properties beyond its enhancement of BRCA1-mediated growth suppression (1). That report also identified a cell line, the NCI-H226 non-small cell lung cancer cell line (H226 cells), that did not express BAP1 mRNA or protein (1). This cell line has provided an extremely useful tool in which to characterize the possible growth and/or tumor suppressive effects of BAP1. Another necessary tool for these analyses was a high affinity, and highly specific, antibody directed against BAP1. Monoclonal antibodies with epitopes directed to different regions of BAP1 were prepared and characterized. Immunoprecipitation analysis of ³⁵S-labeled *in vitro* transcribed and translated BAP1 protein showed that each of the antibodies detected BAP1 with the 3C11 isolate showing the strongest reactivity of the three monoclonal antibodies. Western analysis showed that BAP1 was expressed in several cell lines at similar levels. Since the monoclonal isolate 3C11 delivered the strongest signal in these assays (the polyclonal antibody does not appear to work in Western analysis) it was routinely used throughout the experiments described below.

Monoclonal antibody 3c11 production: The human BAP1 cDNA was fused (in frame) downstream of the 6 Histidine residues of the vector pQE-30 (QIAGEN, Inc.). The His-tagged protein was purified from *E.coli* over a Ni-agarose column. 50 µg of recombinant 6XHis-BAP1 fusion protein, in 50 µl PBS, was emulsified in complete Freund's adjuvant and injected s.c. into Balb/c mice followed by 3 boosts in incomplete Freund's adjuvant. The 4th boost was given i.v. and the splenocytes were fused three days later with the mouse non-Ig secreting cell line P3X63Ag8.SP2/0. Hybridomas were selected by testing supernatants by ELISA on several recombinant GST fusion proteins: GST-BAP1 (amino acids 1-250), GST-BAP1 (amino acids 300-480) and GST-BAP1 (amino acids 494-729). Clones that recognized these subregions were selected, subcloned, and tested for activity via Western blot analysis and ELISA. A subset of these clones was then developed further. All resulting monoclonal antibodies were of the IgG1, kappa subtype. The BAP1 3c11 mAb (Oncogene Sciences, Inc.) recognizes an epitope in the region spanning amino acids 240-598 of human BAP1.

Cell lines expressing wild-type BAP1 and mutant BAP1 [the enzymatically inactive BAP1s (C91S, or A95D, or G178V) or containing the expression vector pcDNA3 alone were generated by Ca²⁺-phosphated-mediated transfection of the H226 cell line. After selection of clones positive for growth in 0.2 mg/mL G418, cell lines expressing both high and low levels of wild type or mutant BAP1 were selected and assayed for changes in cell morphology, cell growth rate, anchorage-independent growth and *in vivo* tumorigenesis. Experiments performed in our standard growth medium (RPMI + 10% FCS) showed no differences in the growth rates between any of the cell lines (data not shown). However, when the concentration of growth

factors was decreased five-fold (i.e. 2% FCS), differences in the growth rates of the individual cell lines became apparent. The cell lines expressing a higher level of wild-type BAP1 grew at a slower rate compared with the vector cell lines, while cell lines expressing lower levels of BAP1 grew at a rate similar to the vector lines. This same general pattern was also seen with the BAP1(C91S) cell lines suggesting that the level of BAP1 protein in the cell was important to its effects on cell growth. Furthermore, the BAP1 cell lines generally grew slower than the BAP1(C91S) cell lines, suggesting that the enzymatic activity of BAP1 is important in mediating cell growth. Expression of BAP1 in the H226 cells gave rise to clones that differed in their appearance (as grown on plastic tissue culture dishes) when compared to all other H226 cell lines. The vector, BAP1(C91S), and the "low expressing" wild-type BAP1 cell lines all had the same appearance, being generally cubical in shape, with nuclei off-center, and growing in tightly packed colonies when plated thinly. In contrast, cells expressing high levels of BAP1 were round in shape, with the nucleus centered within the cell, and growing in patches; The cells touched each other but did not pack together. These characteristics remained even after these cells reached confluence. None of the cells noticeably "piled-up" when over-grown for extended periods of time (up to 4 weeks; data not shown).

BAP1 effectys on anchorage-independent cell growth and tumor suppression in SCID mice: The change in morphology of the H226 cell upon expression of BAP1 prompted an investigation into BAP1's effect on anchorage-independent cell growth. All cell lines grew slowly on soft agar, with the parental, vector, and BAP1 cell lines showing no difference in the size of their colonies or their ability to form colonies. However, the BAP1(C91S) cell line showed slightly larger colonies after the same period of growth, suggesting that loss of BAP1's enzymatic activity may be important in the progression to a more motile cell state. To determine whether the expression of BAP1 would affect the tumorigenicity of the NCI-H226 cells, CB17 SCID mice were injected with 5 distinct cell lines over two experiments. The first experiment involved only the comparison of vector and wild-type BAP1. Five mice were each injected with 5×10^6 cells of each cell line. All mice had tumors by the end of the experiment (42 days), however, the tumors from the BAP1 mice were significantly smaller than those from the vector mice, and the mice injected with vector cells had palpable tumors earlier (data not shown). After excision, tumors were assayed for the expression of BAP1 by Western analysis. The tumors derived from cells expressing BAP1 were no longer expressing the BAP1 protein, suggesting either that these cells had lost their ability to express BAP1 or that a contaminating sub-population of cells which were not expressing BAP1 had grown out during the experiment. To confirm and expand these results, a second experiment was performed in which vector and BAP1 cell lines, distinct from those of experiment 1, were injected into SCID mice. A BAP1(C91S) cell line was included in this experiment to determine the effect of the loss of BAP1's enzymatic activity on tumorigenicity. Mice injected with cells expressing BAP1 developed no tumors while those mice injected with cells expressing vector or BAP1(C91S) developed tumors of the same size and at about the same rate. Tumors derived from cells expressing BAP1(C91S) continued to express this protein as determined by Western analysis. Although the time period for this experiment was shorter than the previous experiment (30 days vs. 42 days), any developing tumors should have been detected at this point since tumors were detectable at this point in all mice of experiment 1.

Thus, this work accomplished in the last period of DoD funding has firmly established that BAP1 is a tumor suppressor gene. Cell lines which lack BAP1 show a highly transformed morphology and grow aggressively in both anchorage independent growth models and in tumor xenografts *in vivo*. However, re-introduction of wild type BAP1 into these cells reverses and/or suppresses the malignant phenotype. Moreover, tumors in mice which do grow after long latencies have either deleted or inactivated expression of the BAP1 transgene, consistent with a tumor suppressor role. Most interestingly, the tumor suppressor function of BAP1 is absolutely dependent on its ubiquitin hydrolase enzymatic activity as a point mutation which changes the catalytic cysteine, no longer functions as a growth suppressor. These findings are the first to implicate a ubiquitin hydrolysis enzyme in cellular growth control. Furthermore, our findings strongly suggest that the UCH enzymatic domain of BAP1 should be a target for mutation in primary human tumor specimens.

The possibility that BAP1 may be a tumor suppressor gene suggested that its deletion might play a critical role in tumor pathogenesis. We questioned whether BAP1 might be located at a chromosomal region routinely mutated in breast cancer. As part of the original SOW (task 13), we are at present searching for such mutations using PCR and SSCP taking advantage of the known genomic structure of human BAP1 which we have solved (in preparation). Thus far more than 120 tumors have been screened by PCR-SSCP. The full-length BAP1 cDNA was used in fluorescent *in situ* hybridization (FISH) to identify the chromosomal location of the *BAP1* gene. Specific signals were observed only on the midportion of chromosome 3 with 42 of 69 analyzed metaphase spreads showing at least one specific signal. The FLpter value was 0.27 ± 0.02 , corresponding to a localization for BAP1 at 3p21.1-p21.31. This location is a region of LOH for breast cancer as well as a region routinely deleted in lung carcinomas.

The chromosomal location of *BAP1* suggested the possibility of mutations within *BAP1* in tumor samples. Thus, a variety of tumor samples were screened for mutations within the *BAP1* gene by Southern, Northern and PCR-based SSCP analyses. Genomic DNAs from a panel of small cell lung cancer (SCLC), non-small cell lung cancer (NSCLC), breast cancer, and lymphoblastoid cell lines, were subjected to EcoR1 digestion and then hybridized to a radio-labeled, full-length BAP1 probe. A single 23 kb band was detected in the lymphoblastoid and most tumor cell lines. One NSCLC line, H226, did not show the 23 kb band but did show an aberrant approximately 30 kb band. To further characterize this potential genomic rearrangement, we subjected genomic DNA from H226 and a smaller number of lung cancer and lymphoblastoid lines to BamH1 digestion. Using the full-length BAP1 probe, we detected four distinct bands at 7.5 kb, 4.0 kb, 3.0 kb, and 2.4 kb which were present in all cell lines tested with the exception of H226. In the H226 line, we detected only the 2.4 kb band and an aberrant 2.6 kb band. Further mutational analysis of BAP1 was performed by screening a panel of lung cancer and lymphoblastoid cell lines for expression of the BAP1 mRNA. Northern analysis showed that most cell lines expressed a single ~4 kb mRNA. However, two cell lines, H226 and H1466 (both NSCLCs), showed undetectable levels of BAP1 expression (a not unexpected result for sample H226) suggesting that BAP1 may play a critical role in NSCLC pathogenesis. Finally, a panel of lung and breast cancer cell lines were screened for mutations in the BAP1 open reading frame by RTPCR-SSCP. We detected a homozygous 8 base pair deletion in the cDNA from the NSCLC line H1466. This short deletion leads to a frameshift and encodes a 393 amino acid protein. This

homozygous deletion was confirmed to be present in genomic DNA from the same cell line. These data clearly show that genetic alterations, including intragenic homozygous deletions, occur in BAP1. Our preliminary results suggest that a low frequency of mutation occurs, however, they often inactivate the UCH enzymatic domain as would be predicted from the results above.

We have also tested whether BRCA1 might be a direct substrate for the UCH activity of BAP1 and whether BAP1-mediated deubiquitination of BRCA1 would be expected to stabilize the protein and protect it from proteasome-mediated degradation (partial task 14). This scenario would be consistent with both the ability of co-transfected BAP1 to enhance the tumor suppressor effects of BRCA1 in colony formation assays and the finding of mutations in BAP1 in cancer cell lines. We found that the stably transfected NCI-H226 cells that are deficient in BAP1 express the same level of BRCA1 protein as three independent stable NCI-H226 cell clones expressing wild-type BAP1. Furthermore, BRCA1 levels were unchanged in H226 cell clones expressing mutant BAP1 proteins containing point mutations: C91S, A95D, and G178V, or large deletions: BAP1 Del UCH or BAP1 Del BID, or the hybrid UCH-L3 BAP1. In addition, DNA sequencing and SSCP analysis showed that BRCA1 was wild-type in the NCI-H226 cells. These results also suggest that BAP1 does not stabilize BRCA1 by rescue from proteasome-mediated degradation. However, these findings do not exclude the possibility that a substrate for BAP1 UCH activity may be another BRCA1-associated protein whose possible UCH-dependent stabilization or targeting is important for function of the BRCA1 complex. The work described above and the conclusions derived therefrom were performed in accordance with the original statement of work, addressed below:

Specific Aim 1: Characterize interaction of BRCA1 and S6.

Task 1: Establish vectors/reagents/proteins required for association.

Completed, published in references 1, 13.

Task 2: Develop in vitro association assay and in vitro kinase assays.

Completed, unpublished, we could not confirm in vitro association of proteins.

Task 3: Determine ability of BRCA1-RF to modulate S6 kinase activity.

Not addressed due to results of TASK 2.

Task 4: Determine if BRCA1 is a substrate of S6 and map regions required.

Not addressed due to results of TASK 2.

Task 5: Prepare deletions mutations of BRCA1 and S6 kinase to map interaction.

Completed, published in reference 1.

Specific Aim 2: Characterize the BRCA1 associated protein BAP-1.

Task 6: Isolate full-length cDNA clones of BAP-1 and genomic clones.

Completed, cDNA clone published in (1). Genomic clone is not yet published.

Task 7: Sequence cDNA of BAP-1 and determine intron/exon organization of genomic BAP-1.

Completed, in preparation for publication.

Task 8: Prepare recombinant purified BAP-1 and synthetic peptides to coding region.

Completed, published in reference 23.

Task 9: Prepare antibodies to BAP-1 both polyclonal and monoclonal and characterize.

Completed, published in references 1, 23 and in preparation.

Task 10: Isolate in vitro complexes of BRCA1 and BAP-1 via co-immunoprecipitation, and localize BAP-BRCA1 subcellularly. Reconstitute BAP-1/BRCA1 complexes in vitro. **Partially completed. The *in vitro* association of BAP-1 and BRCA1 are published in reference 1. However, this was from complex mixtures and could, therefore, be indirect binding. BRCA1 and BAP-1 have been co-localized in cells (reference 23).**

Task 11: Prepare mutations/deletions of BRCA1 and BAP then map interaction domains. **Completed, published in reference 1.**

Task 12: Determine chromosomal location BAP-1 and promotor structure of BAP-1. **Partially completed: Human BAP-1 chromosomal location was published in reference 1. The promotor structure analysis is ongoing.**

Specific Aim 3: Characterize BAP-1/BRCA1 in primary breast cancer specimens and look for mutations in BAP-1.

Task 13: Using intron-exon structure and PCR-SSCP based studies, look for mutation in BAP-1 in primary specimens.

Partially completed. More than 120 tumors screened so far by PCR-SSCP.

Task 14: Determine if expression of BAP-1 in cultured breast cancer cells influences BRCA-1 function and also determine if BAP-1 itself is a transforming gene in mammary epithelial cells.

Partially completed (see this write up).

WORK UNDERTAKEN NOT IN ORIGINAL SOW

Because of the clear role of BRCA-1 in DNA repair processes, we have begun analysis of BAP-1 in these pathways. This work is in collaboration with Dr. Tony Leadon from UNC whose group published the seminal work on BRCA1 and its role in DNA repair

Key Research Accomplishments:

- We have published a complete characterization of BRCA-1 antibodies (see appendices) and documented the dynamic cell-cycle distribution of BRCA1 in the nucleus.
- We have generated highly specific monoclonal antibodies to human BAP1. The BAP1 3c11 mAb (Calbiochem / Oncogene Sciences, Inc.) recognizes an epitope in the region spanning amino acids 240-598 of human BAP1.
- We have demonstrated that BAP1 is a bonafide tumor suppressor which is capable of suppressing the malignant phenotype of BAP1 null-cells in a transfection assay [(these results are in preparation for submission)]

Key Research Accomplishments (continued):

- We have initiated a comprehension analysis of the mutational status of BAP1 in both primary human breast and lung tumors and in tumor-derived cell lines. Our preliminary results suggest that a low frequency of mutation occurs, however, they often inactivate the UCH enzymatic domain as would be predicted from the results above.
- We have identified that the NCI-H226 cell line is deleted for the BAP1 gene thus represents an important research tool for characterization of BAP1 function. We have generated a panel of stable transfectant cell clones that express either wild type and mutant BAP1 proteins.
- We have demonstrated that BRCA1 levels in H226 BAP (-/-) cells and H226 BAP (+/+) complemented cells are the same, thus it is unlikely that BAP1 stabilizes BRCA1 protein levels.
- We have begun pilot experiments to determine if BAP1 is involved in the BRCA1 pathway of transcription-coupled DNA repair (TCR).

Conclusions:

We have discovered and characterized a novel protein, BAP1, which binds to the BRCA1 RING finger motif. A number of lines of evidence are offered which support a role for BAP1 in BRCA1 signal transduction pathways. Specifically, we showed that; 1) BAP1 binds to the RING finger of BRCA1, but not to tumor-derived mutants of BRCA1 or related RING domains; 2) The BAP1-BRCA1 interaction occurs *in vitro* and BAP1 mRNA is expressed in those tissues which also express BRCA1; 3) BAP1 is a nuclear-localized, ubiquitin carboxy-terminal hydrolase (UCH) which cleaves model ubiquitin substrates *in vitro*; 4) BAP1 enhances BRCA1-mediated suppression of cell growth in colony formation assays and does so in a manner dependent upon the UCH enzymatic domain and the BRCA1-interaction domain; and 5) Human BAP1 maps to 3p21.3 and intragenic, homozygous deletions occur in non-small cell lung cancer cell lines. Together, these observations suggest that BAP1 is a tumor suppressor gene and that it serves either as a regulator or an effector in BRCA1 growth control pathways. In addition, we generated a new monoclonal antibody to BRCA1 and compared it with other anti-BRCA1 antibodies. The general conclusions derived from the comparison of the different BRCA1 antibodies is that 1) they collectively validate the presence of BRCA1 in the nucleus and 2) they can be used to evaluate the redistribution of BRCA1 induced by physiological changes, but only in cells where cross-reactive proteins are absent. We found that the BRCA1 containing nuclear domains are different than any of the well defined nuclear domains. However, a cell cycle-related partial overlap was found for HP1a, a chromodomain-containing protein involved in heterochromatin maintenance. Cellular stimuli, such as heat shock and herpesvirus infection, dispersed BRCA1 from its domains. However, infection with Adenovirus 5 recruited BRCA1 to regions of viral transcription and replication. These disparate distributions of BRCA1 may provide clues to its dynamic function. Both the specificity of the BRCA1 RING finger-BAP1 interaction and the fact that independent, tumor-derived missense mutations in the cysteines in the BRCA1 RING finger domain abolish interaction with BAP1 provide compelling evidence for the physiological relevance of this interaction. Currently we are pursuing the following questions; what are physiologically relevant BAP-1 substrates, the role of BAP-1 in regulating DNA repair, the interaction of BAP-1 with BRCA-2 and finally, the role of BAP-1 overall in ubiquitin-regulated nuclear processes. The support of the US Army Breast Cancer Program has been instrumental in supporting the discovery and characterization of the BAP1 protein, a novel BRCA1 associated protein and has provided a basis for future studies with broad implications relating to ubiquitin metabolism, DNA repair, and tumor suppression.

We have identified a novel protein, BAP1, which binds to the RING finger domain of the Breast/Ovarian Cancer Susceptibility Gene product, BRCA1. BAP1 is a nuclear-localized, ubiquitin carboxy-terminal hydrolase, suggesting that deubiquitinating enzymes may play a role in BRCA1 function. BAP1 binds to the wild-type BRCA1-RING finger, but not to germline mutants of the BRCA1-RING finger found in breast cancer kindreds. BAP1 and BRCA1 are temporally and spatially co-expressed during murine breast development and remodeling, and show overlapping patterns of subnuclear distribution. BAP1 resides on human chromosome 3p21.3; intragenic homozygous rearrangements and deletions of BAP1 have been found in lung carcinoma cell lines. BAP1 enhances BRCA1-mediated inhibition of breast cancer cell growth and is the first nuclear-localized ubiquitin carboxy-terminal hydrolase to be identified. BAP1 may be a new tumor suppressor gene which functions in the BRCA1 growth control pathway.

Keywords: ubiquitin hydrolase; BRCA1; chromosome 3p21.3; RING finger

Introduction

The cloning of the chromosome 17q21 *BRCA1* breast cancer susceptibility gene is a landmark accomplishment in cancer genetics (Miki *et al.*, 1994). Germline mutations in *BRCA1* appear to account for ~50% of familial breast cancers and essentially all families with 17q21-linked inherited susceptibility to ovarian and breast cancer (Szabo and King, 1995). The importance of this gene is underscored by the fact that kindreds segregating constitutional *BRCA1* mutations show a lifetime risk of 40–50% for ovarian cancer and >80% for breast cancer (Easton *et al.*, 1993, 1995). The classification of *BRCA1* as a highly penetrant, autosomal dominant tumor suppressor gene has been genetically confirmed by the finding of frequent LOH of the wild-type allele in breast tumors from mutation

carriers (Hall *et al.*, 1990; Miki *et al.*, 1994; Smith *et al.*, 1992). Surprisingly, *BRCA1* mutations in sporadic breast cancer, including those which show 17 g LOH, have yet to be found and *BRCA1* mutations are extremely rare in sporadic ovarian cancer (Futreal *et al.*, 1994; Merajver *et al.*, 1995).

The *BRCA1* locus spans >100 kb comprising 24 exons (Miki *et al.*, 1994). More than 100 constitutional mutations have been identified in *BRCA1* over the entire length of the gene. Some clustering of these mutations has been seen in populations, and genotype-phenotype correlations have been suggested (FitzGerald *et al.*, 1996; Ford *et al.*, 1994; Muto *et al.*, 1996; Roa *et al.*, 1996; Struwing *et al.*, 1995). The majority of germline mutations result in a truncated BRCA1 protein although recurrent missense mutations resulting in amino acid substitutions in kindreds have also been observed (Couch and Weber, 1996). The heterogeneity of BRCA1 mutant proteins produced by this spectrum of genetic mutations suggests that multiple, independent functions and/or protein-protein interaction surfaces are targets for mutational inactivation. However, the biochemical functions of BRCA1 are largely unknown.

The predominant *BRCA1* mRNA of 8.0 kb encodes a 1863 amino acid protein with only a few sequence motifs suggestive of function (Miki *et al.*, 1994). There are two highly conserved regions. The first is the 100 amino acid N-terminus which encodes a RING finger motif, a domain that is predicted to bind zinc and may be a protein-protein interaction motif (Borden *et al.*, 1995; Lovering *et al.*, 1993). The second region is at the C-terminus which contains an acidic region and two copies of a novel motif, designated the BRCT domain. The BRCT domain is present in a variety of putative cell-cycle related proteins, including RAD9 and 53BP1 (Koonin *et al.*, 1996). The most abundant BRCA1 protein is apparently a ~220 kDa phosphoprotein which is predominantly, but apparently not exclusively, nuclear in subcellular distribution (Chen *et al.*, 1995, 1996b; Scully *et al.*, 1996). BRCA1 is localized to discrete nuclear dot structures in a cell-cycle-dependent manner (Scully *et al.*, 1997b). Other isoforms of BRCA1 have been detected including a protein of 97 kDa. This smaller form lacks exon 11, and thus a functional nuclear localization signal, and is presumably the result of an alternative splicing event (Thakur

et al., 1997). The above observations, coupled with the finding of a BRCA1 COOH-terminal domain capable of activating transcription as a Gal4 DNA-binding domain fusion (Chapman and Verma, 1996) and the co-fractionation of BRCA1 with the RNA pol II holoenzyme (Scully *et al.*, 1997a), suggest a role for BRCA1 in transcriptional regulation.

The expression patterns of *BRCA1* further support its role in growth regulation and/or differentiation. The spatial-temporal expression pattern in the embryonic mouse includes the neuroepithelium, and epithelial lineages of the skin, kidney and mammary gland (Marquis *et al.*, 1995). Moreover, *BRCA1* mRNA is sharply increased in alveolar and ductal cells of the breast epithelia during pregnancy (Marquis *et al.*, 1995). Consistent with this, *BRCA1* transcription is under (indirect) hormonal control in both cell culture and organismal systems (Gudas *et al.*, 1995, 1996; Vaughn *et al.*, 1996; Marks *et al.*, 1997). *BRCA1* is also highly expressed in the adult testis during the final stages of meiosis and spermiogenesis (Zabludoff *et al.*, 1996). Together, these observations suggest a broad role for BRCA1 in terminal differentiation events in multiple tissues. Somewhat paradoxically, the murine *brca1*^{-/-} embryos die very early in gestation and exhibit severe cell proliferation defects and profound cell cycle arrest (Hakem *et al.*, 1996; Liu *et al.*, 1996). The association of *BRCA1* expression with both proliferation and differentiation events suggests a possible role for BRCA1 in regulating a genetic program which prepares the cell for terminal differentiation and possibly maintains that phenotype. Results of cell culture and transfection studies have underscored the tumor suppression function of BRCA1, but have revealed little of possible mechanisms. *BRCA1* antisense expression can transform fibroblasts and accelerates growth of breast cancer cell lines (Rao *et al.*, 1996; Thompson *et al.*, 1995). Expression of wild-type *BRCA1* inhibits colony formation and tumor growth *in vivo*, whereas tumor derived mutants of *BRCA1* lack this growth suppression activity (Holt *et al.*, 1996).

Evidence of a role for BRCA1 as a terminal differentiation checkpoint has recently been provided by the finding that BRCA1 and the RAD51 protein (involved in DNA recombination/repair) are co-localized and physically associated in mitotic and meiotic cells (Scully *et al.*, 1997b). The co-localization of BRCA1 and RAD51 on synaptonemal meiotic chromosomes suggests a role for this complex in either the fidelity of DNA replication, cell-cycle progression or genomic integrity. Though intriguing, these results do not suggest a function for BRCA1 which, when lost through mutation of the BRCA1 gene, would give rise to tumors. Strategies based upon identification of proteins which bind to BRCA1 have yielded components of the nuclear import pathway (Chen *et al.*, 1996a) and a novel RING finger/BRCT-domain-containing protein, BARD1 (Jin *et al.*, 1997; Wu *et al.*, 1996). However, none of these associated proteins have suggested a function for BRCA1.

We have chosen to focus upon the highly conserved BRCA1 RING finger domain as a potential protein-protein interface. This motif is defined by a spatially conserved set of cysteine-histidine residues of the form C₃HC₄. Structural analysis of the motif shows that two

molecules of zinc are chelated by the consensus residues in a unique 'cross-braced' fashion (for reviews, see; Klug and Schwabe, 1995; Saurin *et al.*, 1996). Comparative structure analyses suggest that the RING fingers have a common hydrophobic core structure but that the region encoded by amino acids spanning cysteines 24 and 64 (for BRCA1) forms a highly variable loop structure which may be the determinant of protein-protein interaction specificity. The RING motif occurs in over 80 proteins including the products of proto-oncogenes and putative transcription factors (Saurin *et al.*, 1996). Evidence that the RING finger domain functions as a protein-protein interface has come from the study of the proto-oncogene PML (Borden *et al.*, 1995) and the transcriptional co-repressor KAP-1 (Friedman *et al.*, 1996). Intriguingly, like BRCA1, both PML and KAP-1 are localized to discrete, non-overlapping, nuclear dot structures, and mutations in the RING finger of PML abolish its localization to these dot structures (Borden *et al.*, 1995).

We hypothesize that the BRCA1 RING finger is a binding site for protein(s) which either mediate BRCA1 tumor suppressor function or serve to regulate these functions. Genetic evidence supports this in that single amino-acid substitutions at metal chelating cysteines, C61G and C64G, occur in *BRCA1* kindreds; these mutations segregate with the disease susceptibility phenotype and are predicted to abolish RING finger structure. We have used the yeast two-hybrid system to isolate proteins which bind to the wild-type BRCA1 RING finger but not to the C61G or C64G mutated RING fingers or other closely related RING fingers. We have isolated mouse and human clones of a novel protein, BRCA1 associated protein-1 (BAP), which fulfils these criteria. BAP1 is a novel, nuclear-localized enzyme which displays the signature motifs and activities of a ubiquitin carboxy-terminal hydrolase. Full-length BRCA1 binds to BAP1 *in vitro* and enhances the growth suppression properties of BRCA1 in colony formation assays. The human *BAP1* locus was mapped to chromosome 3p21.3, and homozygous deletions of *BAP1* were found in non-small cell lung cancers. Together, these data suggest that *BAP1* is a key player in the *BRCA1* growth suppression pathway, and may itself be a tumor suppressor gene. The identification of BAP1 as a ubiquitin hydrolase implicates the ubiquitin-proteasome pathway in either the regulation, or as a direct effector, of BRCA1 function. BAP1 is the first nuclear-localized ubiquitin carboxy-terminal hydrolase to be identified, and may play a broad role in ubiquitin-dependent regulatory processes within the nucleus, including the emerging roles of ubiquitin conjugation as a post-translational modification which alters protein function and or subcellular targeting.

Results

A yeast two-hybrid screen for BRCA1 RING finger interacting proteins

We constructed a synthetic *BRCA1* gene encoding the amino-terminal 100 amino acids of human BRCA1 using long oligonucleotides and PCR-mediated over-

lap-extension gene synthesis techniques (Madden *et al.*, 1991). Codon usage was optimized for expression in *E. coli* and *S. cerevisiae*. The resulting gene was fused to

the LexA DNA binding domain (Figure 1b). The negative control/specificity controls included: (1) the Cys61Gly, Cys64Gly, Met18Thr and Arg71Gly muta-

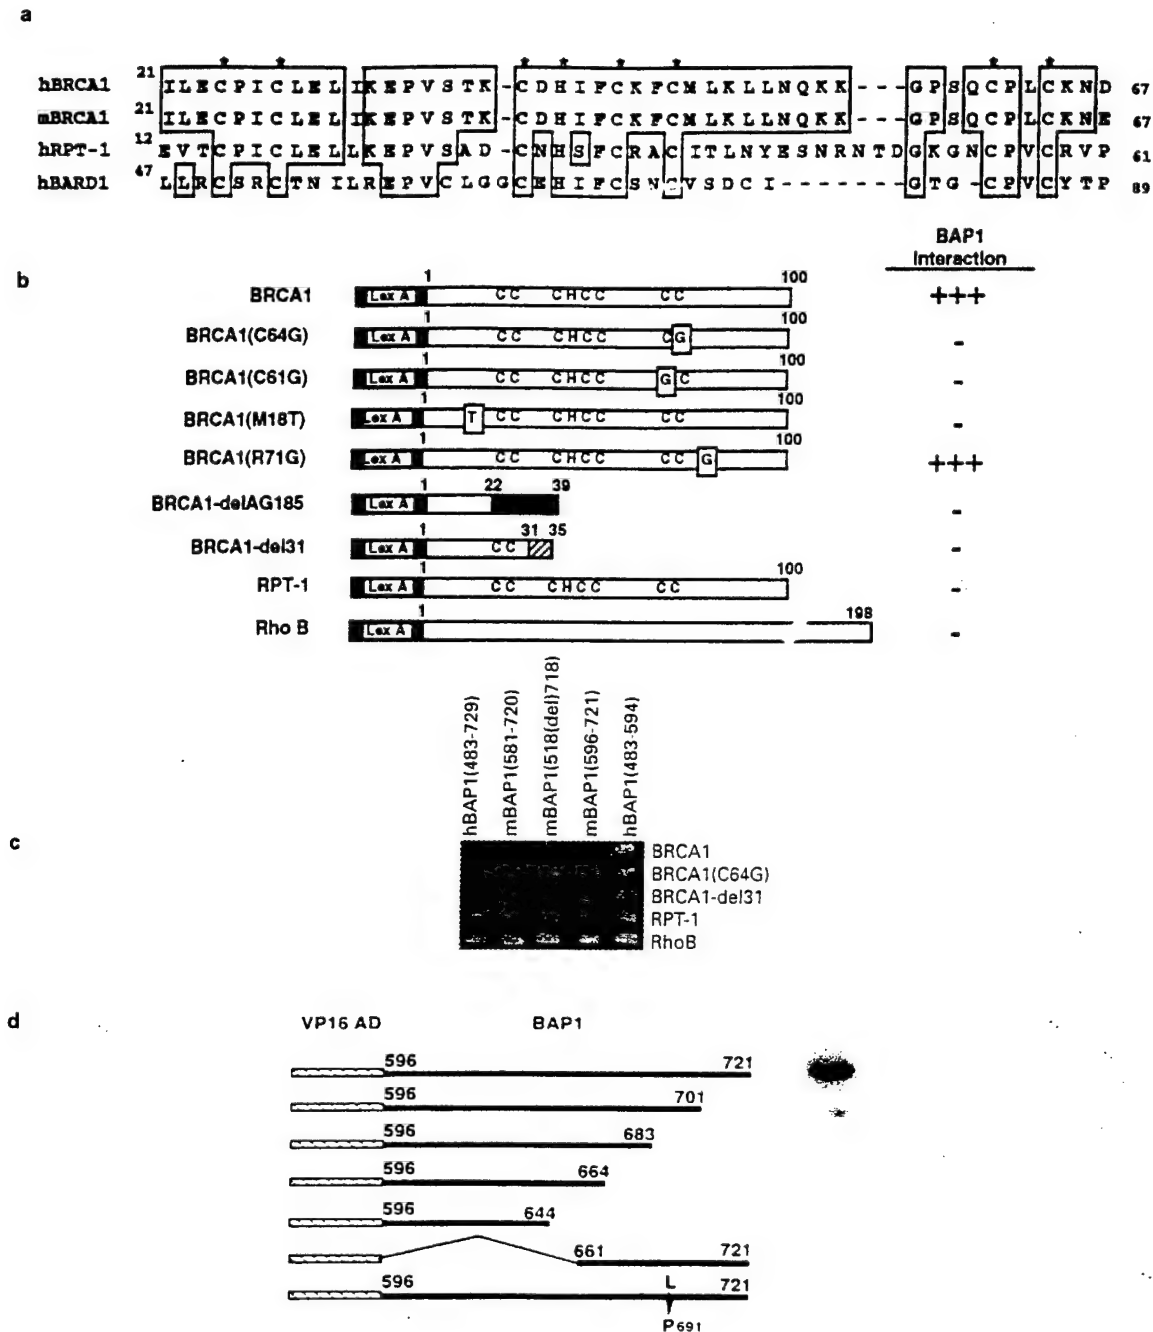

Figure 1 BRCA1 RING finger domain binds a novel protein. (a) Alignment of the RING finger domains of human and mouse BRCA1 (AA's 21–67), RPT-1 (AA's 12–61; the most closely related RING finger) and BARD1 (AA's 47–89). Asterisks (*) identify the Zn-chelating amino acids that form the core of the RING finger. Boxed amino acids show regions of identity between the RING finger domains of human BRCA1 and the other proteins. Alignment performed by CLUSTALW (Thompson *et al.*, 1994). (b) The amino-terminal 100 amino acids of human BRCA1 (which includes the RING finger domain) or the indicated amino acids of the various BRCA1–RF mutants and controls were fused to the LexA DNA-binding domain. Expression of all fusions in yeast was confirmed by Western analysis. A summary of the two-hybrid interaction between the Gal4-hBAP1(483–729) fusion clone and the various LexA–RING finger fusions is shown. (c) The BRCA1-interacting protein specifically interacts with the BRCA1 RING finger domain. Two hybrid screens of a human B-cell library and a mouse embryo (9.5–10.5 days) library identified a protein that interacted with wild type BRCA1–RF, but not with BRCA1-del31 (a truncated BRCA1), BRCA1(Cys64Gly) (a BRCA1–RF containing a point mutation), RPT-1 (a RING finger closely resembling the BRCA1), or RhoB (a non-related protein). Dark color of yeast indicates transcription from the LacZ reporter gene. Clones obtained from the two libraries are described as partial BAP1 proteins with AAs in parentheses. h, human; m, mouse. (d) The two-hybrid interaction between the BRCA1 RING domain and BAP1 requires the BAP1 C-terminal domain. Murine clone mBAP1(596–721) defines a portion of the BRCA1-interaction domain of BAP1. Mutants of this clone were generated by PCR-based deletion or point mutagenesis of mBAP1(596–721) as described in Materials and methods. Each individual mutant was co-transformed with LexA–BRCA1–RF into yeast and tested for interaction via its ability to activate transcription from the LacZ locus. Expression of all fusions in yeast were confirmed by Western analysis

tions that occur in *BRCA1* families; (2) the protein equivalent of the del AG185 mutation which results in a frame-shift at amino acid 22 followed by 17 out-of-frame amino acids and a stop codon; (3) a truncated

BRCA1 RING finger at amino acid 31, the result of a PCR error; (4) the RPT-1 RING finger domain, a putative lymphocyte-specific transcription factor, whose RING finger domain is most highly related to

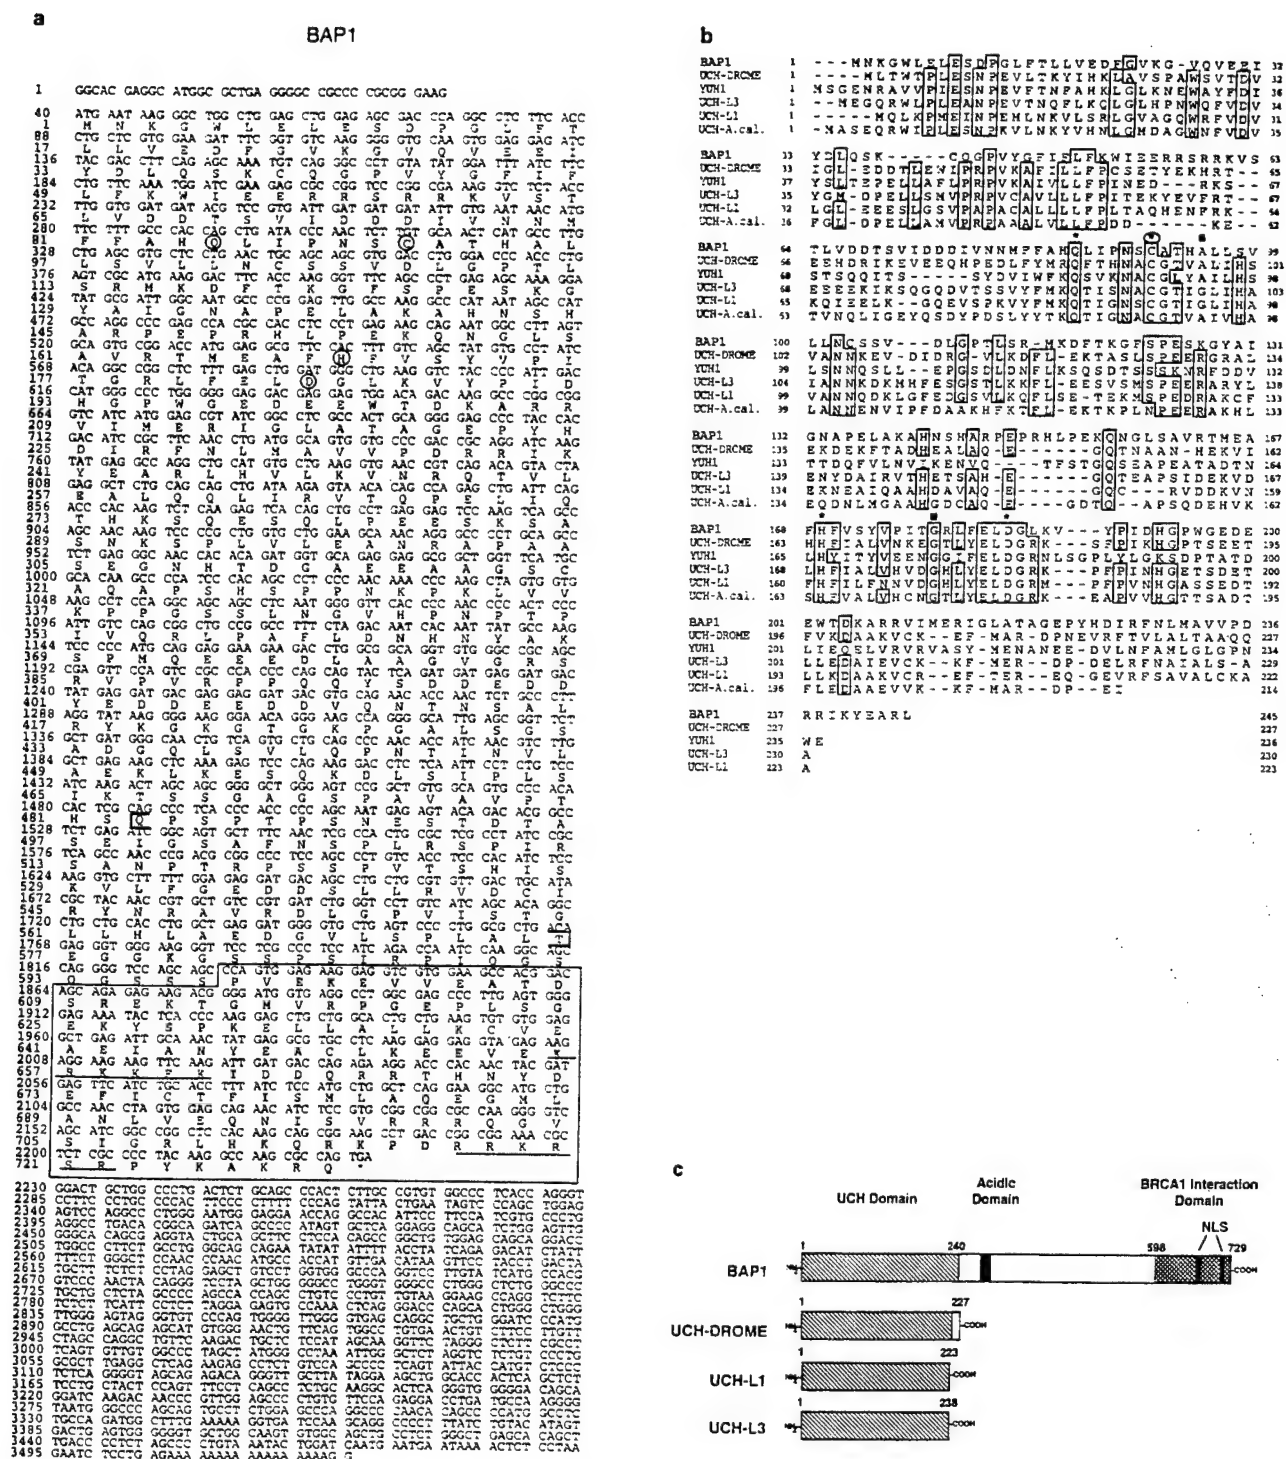

Figure 2 BAP1 is a novel ubiquitin carboxy-terminal hydrolase (UCH). (a) The nucleotide and amino acid sequence of BAP1. The longest open reading frame which contained the amino acids defined by the human 2-hybrid fusion protein is 2188 nucleotides encoding 729 amino acids. The cDNA also contains 39 nucleotides of 5'UTR and 1295 nucleotides of 3'UTR. The enzymatic active site is contained within the first 250 amino acids; the active site residues are circled. The putative nuclear localization signals (NLS) are underlined. The BRCA1-interaction domain is boxed and the protein fragment used to generate BAP1 polyclonal antibodies is bracketed (AAs 483–576). (b) Comparison of BAP1 with other UCH's. UCH DROME (genebank #P35122), YUH1 (genebank #P35127), UCHL-1 (genebank #PO9936), UCHL-3 (genebank #P15374), UCH A.cal. (genebank #U90177). The BLAST search algorithm was used to identify proteins closely related to BAP1 (Altschul *et al.*, 1990). The UCH domain of five of these proteins were aligned with BAP1 using the CLUSTALW (ver.1.6) algorithm (Thompson *et al.*, 1994). Residues conserved between species with an identity of 85% or greater are boxed. Active site residues are denoted with asterisks. The catalytic cysteine is marked with a circled asterisk. (c) Diagrammatic comparison between BAP1 and some of the other UCH family members

that of BRCA1 (Patarca *et al.*, 1988); and (5) a LexA fusion with RhoB. The wild-type BRCA1 RING finger (BRCA1-RF) did not display intrinsic transcriptional activation function in yeast, and expression of each LexA fusion in yeast was confirmed by Western blot analysis with anti-LexA antibody (data not shown).

Guided by the expression patterns of BRCA1 during mouse development and in human spleen, we chose to screen cDNA libraries constructed from E9.5-10.5d whole mouse embryos and human adult B cells with the LexA-BRCA1-RF. Thirty-one cDNAs which specifically interacted with BRCA1-RF were obtained: eight of these (three from the human library and five from the mouse library) encoded the same amino acid sequence. These were designated BRCA1 Associated Protein-1 (BAP1) and pursued further. Each clone shares the same translational reading frame with respect to the transcriptional activation domain to which it is fused. In addition, the fusion junctions were different among the clones, suggesting that the interaction was not due to a fusion-junction artifact. Furthermore, the hBAP1 (483-729) and the BRCA1-RF interacted strongly in a mammalian two-hybrid assay (data not shown). The longest BAP1 cDNA retrieved in the two-hybrid screen was a ~2.0 kbp clone from the human library and encoded 246 amino acids followed by a 1.3 kb 3'UTR. Each murine clone encoded an overlapping, smaller subset of this human open reading frame with a human-murine AA sequence identity of 100% over the COOH-terminal 100 AAs (data not shown). Both human and mouse clones showed a strong interaction with the wild-type BRCA1-RF and BRCA1 (Arg71Gly) substitution, but failed to interact with the C64G, C61G, del31, delAG, RPT-1, RhoB, or a variety of other LexA fusion constructs (Figure 1b,c and data not shown).

Further definition of this highly conserved interaction domain was performed by mutagenesis of this region of BAP1. Deletion of protein sequence from the carboxyl or amino termini of mBAP1(596-721) almost completely destroyed the BAP1-BRCA1 interaction (Figure 1d), possibly suggesting an extended interface between the proteins. Interestingly, the mBAP1(518del718) clone interacted most poorly with BRCA1-RF (Figure 1c) and lacked a 93 bp sequence (the reading frame was maintained), possibly the result of a naturally occurring splice variant. That BAP1 also failed to bind multiple, independent tumor-derived mutations of the BRCA1-RF provides strong evidence for the relevance of this interaction to the functions of BRCA1.

Analysis of the BAP1 cDNA

A full-length cDNA was constructed using two IMAGE consortium EST clones and RT-PCR (Figure 2a; see Materials and methods). The BAP1 cDNA comprises 3525 bp; a polyA tract is present along with multiple polyA signals. Conceptual translation yields a long open reading frame of 729 amino acids with a predicted MW of 81 kDa and pI of 6.3. The presumptive initiator methionine is within a favorable context for translation start, however the short 5'UTR of 39 bp encodes amino acids in-frame with the presumptive methionine and does not contain

Figure 3 BAP1 has ubiquitin hydrolase activity. BAP1, or an enzymatically null mutant, BAP1(C91S), were expressed in bacteria by IPTG induction. Bacteria were harvested, lysed and supernatant (Sup) and pellet (Ppt) fractions generated. Each fraction was then measured for UCH activity (bar diagram: n.d., not detected). Induction of protein was verified by SDS-PAGE of each fraction. Arrow indicates BAP1 and BAP1(C91S) protein

a stop codon. Computer database searches indicated that BAP1 is a novel protein with the amino-terminal 240 amino acids showing significant homology to a class of thiol proteases, designated ubiquitin C-terminal hydrolases (UCH), which are implicated in the proteolytic processing of ubiquitin (Wilkinson *et al.*, 1989). These enzymes play a key role in protein degradation via the ubiquitin-dependent proteasome pathway. Similarities to other mammalian UCHs (UCH-L3 and UCH-L1) have been found (Figure 2b and c). Most importantly, the residues which form the catalytic site (Q85, C91, H169 and D184) are completely conserved, including the FELDG motif (Larsen *et al.*, 1996). In addition, a loop of highly variable sequence, which is disordered in the crystallographic structure of human UCH-L3 (Johnston *et al.*, 1997), is present (residues 140-167). This loop may occlude the active site or provide substrates specificity for the enzyme.

BAP1 has a number of additional motifs: a region of extreme acidity spanning amino acids 396 to 408, as well as multiple potential phosphorylation sites and N-linked glycosylation sites (Figure 2a). The C-terminal one-third is highly charged and is rich in proline, serine and threonine. The extreme C-terminus contains two putative nuclear localization signals, KRKKFK and RRKRSR and is hydrophilic, it is predicted to fold into a helical (possibly coiled-coil) structure (Figure 2a;

Figure 4 BAP1 and BRCA1 interact *in vitro* and *in vivo*. (a) BRCA1 and GST-hBAP1(483–729) interact *in vitro*. GST, GST-hBAP1(483–729) and GST-hBAP1(483–594) fusion proteins were expressed in *E. coli* and purified as described in Materials and methods. The Glutathione-Sepharose resins, containing an equivalent amount of fusion protein, were incubated in batch with *in vitro*-expressed, ^{35}S -labeled, BRCA1. After extensive washing, the proteins which remained bound were analysed by SDS-PAGE and fluorography. Lane 1, Input 2% of the labeled BRCA1 used in the associations with the glutathione resins. Lane 2, molecular weight markers. Lane 3, proteins bound to GST alone. Lane 4, proteins bound to GST-hBAP1(483–729). Lane 5, proteins bound to GST-hBAP1(483–594), a fusion protein lacking the BRCA1-interaction domain. Arrow indicates the BRCA1 protein. (b) Co-immunoprecipitation of BRCA1-Δ11 and BAP1. COS1 cells, transiently transfected with BRCA1-Δ11, BAP1, or BRCA1-Δ11 and BAP1 together, were treated with DMSO (–) or with 25 μM ALLN (–) for 16 h. Whole cell extracts were prepared after metabolic labeling and then immunoprecipitated with anti-BAP1 antibody (BAP1) or with anti-BRCA1 antibody, C20 (BRCA1) as indicated. Immunoprecipitated proteins were visualized by SDS-PAGE and fluorography. The BAP1 and BRCA1-Δ11 proteins are indicated. (c) BRCA1 and BAP1 partially co-localize in the nucleus. Asynchronous Rh30 cells were co-stained with the BRCA1-specific BR64 monoclonal antibody (green, top and bottom panels; Upstate Biotechnology) and a BAP1 specific, affinity-purified polyclonal antibody (red, middle and bottom panels). Top and middle panels are single color readouts of the dual color bottom panel. Yellow is produced where green and red images overlap.

S Subbiah, personal communication). Indeed, within this domain the mutation of leucine 691 to a proline, a change predicted to disrupt the helical nature of this region, abolished the BAP1-BRCA1 interaction (Figure 1d). This result is consistent with the hypothesis that BAP1 uses a coiled-coil domain to interact with the RING finger domain of BRCA1. This overall architecture suggests that BAP1 is a new, structurally complex, nuclear-localized member of the UCH enzyme family.

BAP1 has UCH activity

To determine whether BAP1 did indeed have UCH enzymatic activity, BAP1 was expressed in bacteria and this protein was assayed for the ability to hydrolyze the glycine 76 ethyl ester of ubiquitin (Ub-OEt; Mayer and Wilkinson, 1989). IPTG-induced expression of BAP1 in bacteria led to abundant protein, most of which was found in an inactive, insoluble form (Figure 3a, 'BAP1 induced-Ppt'). The BAP1 protein found in the soluble

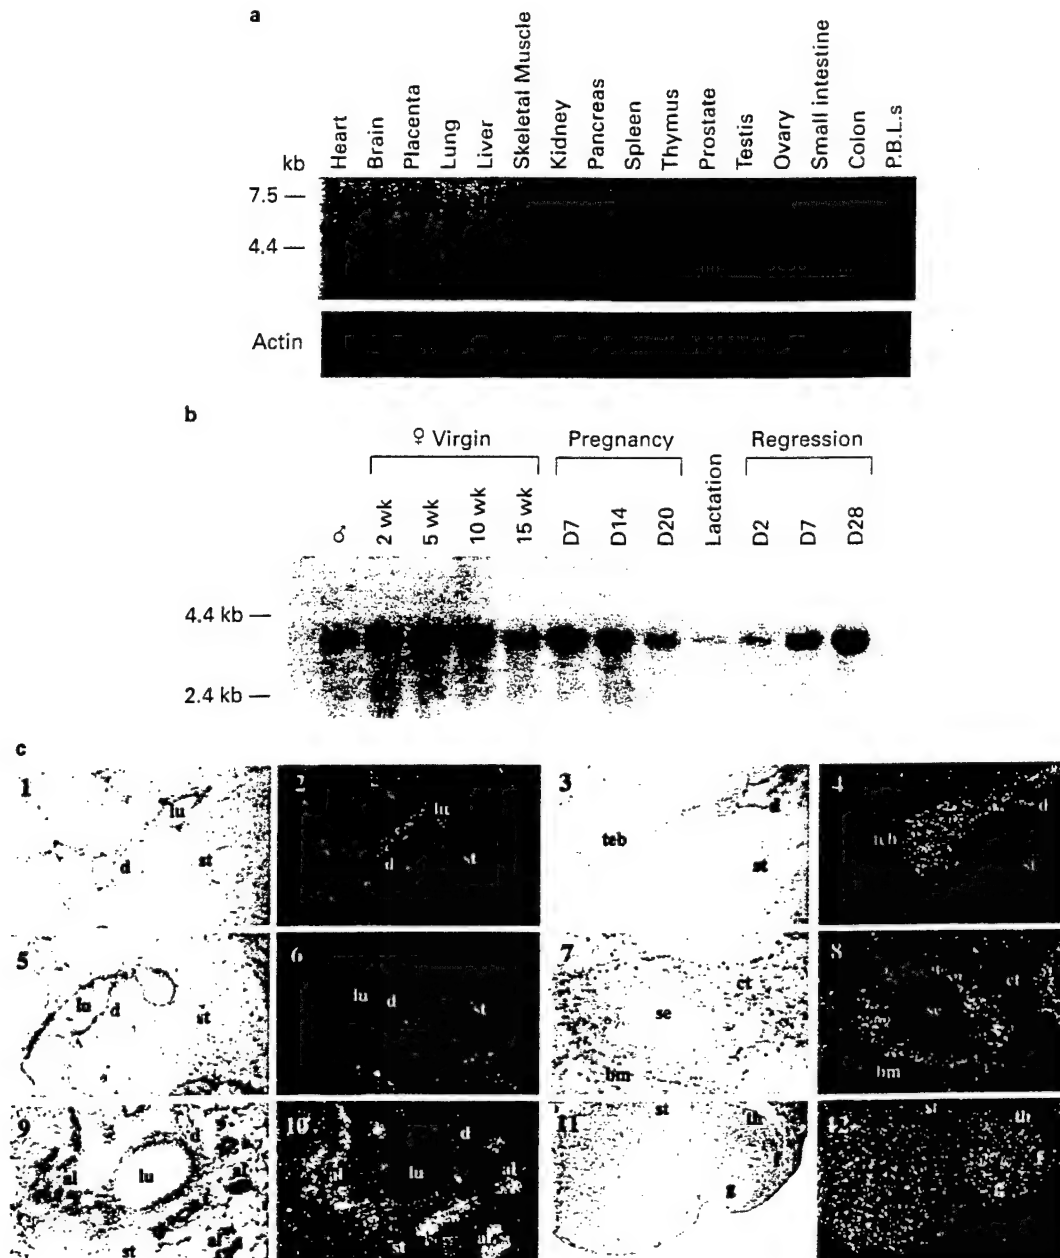

Figure 5 Tissue, spatial and temporal pattern of BAP1 expression. (a) Northern hybridization analysis of human RNA from multiple tissues. Northern blots that contain human RNA from the indicated tissues were probed with ³²P-labeled hBAP1(483–729) cDNA (nts. 1488–3525). The blots were subsequently probed with a muscle actin cDNA. (b) Northern hybridization analysis of *Bap1* expression during mammary gland development. A Northern blot containing poly(A)⁺ RNA isolated from mouse mammary glands at the indicated developmental stages was probed with ³²P-labeled mBAP1(596–721) cDNA. Note that mouse *Bap1* RNA is slightly smaller than the human *BAP1* RNA. (c) *In situ* hybridization analysis of *Bap1* expression. Bright-field (1, 3, 5, 7, 9 and 11) and dark-field (2, 4, 6, 8, 10 and 12) photomicrographs of *in situ* hybridization analyses performed on paraffin sections of mammary glands harvested from adolescent (1–4), mature (5, 6) or pregnant (9, 10) mice. Also shown are sections of testis (7, 8) and ovary (11, 12). To facilitate comparison, dark-field photomicrographs of breast were taken using identical shutter exposure times. al, alveolar bud; d, ductal epithelium; lu, ductal lumen; st, stroma; teb, terminal end bud; d, bm, basement membrane; se, seminiferous tubule; f, developing follicle; g, granulosa cells; th, thecal cells; ct, connective tissue

fraction was able to hydrolyze Ub-OEt, indicating that BAP1 contains UCH-like enzymatic activity (Figure 3b). The active site thiol residue responsible for UCH activity in UCH-L3 has been identified and its mutation leads to abolition of enzyme activity (Larsen *et al.*, 1996). Mutation of the corresponding cysteine residue in BAP1, BAP1(C91S), yielded a protein with no detectable UCH activity (Figure 3b) further supporting the conclusion that BAP1 is a thiol protease of the UCH family.

BAP1 associates with BRCA1 *in vitro* and *in vivo*

Association of BRCA1 with BAP1 was tested *in vitro* by binding of full-length BRCA1 to hBAP1(483–729) fused to glutathione S-transferase (GST; Figure 4a). The ³⁵S-labeled BRCA1, produced by coupled *in vitro* transcription and translation, specifically bound to the GST–hBAP1(483–729) fusion protein, but not to GST alone (Figure 4a) indicating a physical association between the two proteins. As predicted from the yeast two-hybrid results (Figures 1d and 4a), BRCA1 did not bind to GST–hBAP1(483–594), a GST–BAP1 fusion protein lacking the BRCA1 interaction domain.

To determine whether BRCA1 and BAP1 could interact in mammalian cells, a co-immunoprecipitation analysis from co-transfected COS1 cells was performed (Figure 4b). Several attempts to transiently express BRCA1 to any significant level in COS1 cells were without success. Therefore, we performed the analysis with BRCA1-Δ11, a naturally occurring splice variant (Thakur *et al.*, 1997) which can be expressed in these cells and which contains the RING finger domain. The proteasome/caspase inhibitor ALLN (N-acetyl-L-Leuciny-L-Leuciny-L-norLeucinal) was included in the analysis to determine its influence on the stability of the interaction between BRCA1 and BAP1. BRCA1-Δ11 was detected by immunoprecipitation as a sharp band at ~99 kDa in singly transfected COS1 cells (Figure 4b, lane 1). Incubation of a parallel set of transfected cells with ALLN (20 h) prior to harvest revealed a discrete slower migrating band in the anti-BRCA1 immunoprecipitates (Figure 4b, lane 2). Immunoprecipitates from BAP1-transfected COS1 cells revealed a 91 kDa protein whose mobility was apparently unaffected by treatment with ALLN (Figure 4b, lanes 3 and 4). Co-transfection of COS1 cells with BRCA1-Δ11 and BAP1 revealed that these proteins could be co-immunoprecipitated using either anti-BAP1 or anti-BRCA1 antibodies (Figure 4b, lanes 9 and 10); the ability to detect the BRCA1–BAP1 complex under these conditions was dependent upon incubation of the cells with the proteasome inhibitor. In co-transfected, ALLN-treated cells, both forms of BRCA1-Δ11 are evident in the co-immunoprecipitated complex, and both forms are more abundant than singly transfected cells (compare lanes 2 and 10). These results demonstrate the *in vivo* association of BRCA1 and BAP1, and suggest the presence of a proteasome inhibitor-sensitive modification of BRCA1 which may enhance its interaction with BAP1.

To further document the *in vivo* interaction between BAP1 and full-length BRCA1, we determined whether the endogenous (non-transfected) proteins were co-localized in the cell nucleus (Figure 4c). A mouse

monoclonal antibody to BRCA1 (Maul *et al.*, manuscript in preparation) and affinity purified rabbit BAP1 antibody were used to stain rhabdomyosarcoma cells (Rh30), a cell line previously determined to express BAP1 RNA (Jensen and Rauscher, unpublished results). BRCA1 was detected exclusively in punctate domains within the nucleus (excluding nucleoli) in agreement with other reports (Jin *et al.*, 1997; Scully *et al.*, 1997b). BAP1 was also detected in punctate domains within the nucleus of Rh30 cells, however, the number of domains was significantly greater than for BRCA1. Several of the BRCA1 domains coincided with BAP1 domains (yellow dots in the bottom panels), suggesting an endogenous BRCA1–BAP1 interaction. We also detected BRCA1 reactive domains which were not co-localized with BAP1 domains as has been seen with other BRCA1-interacting proteins (Figure 4c; Jin *et al.*, 1997; Scully *et al.*, 1997b). These data show that BAP1 and BRCA1 can physically interact *in vitro* and *in vivo*, and have overlapping subnuclear expression patterns.

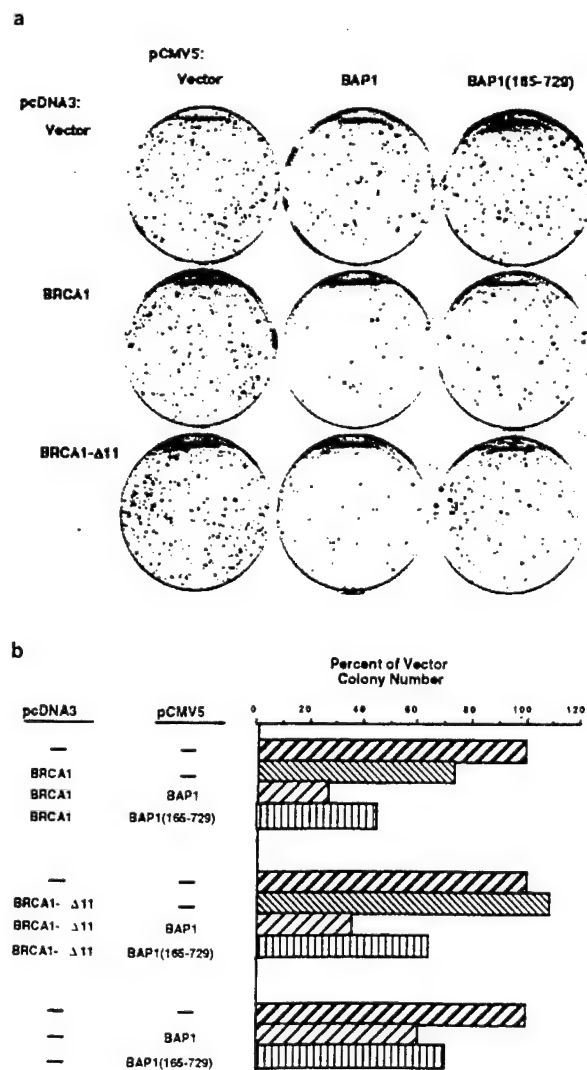

Figure 6 BAP1 enhances BRCA1-mediated growth suppression. (a) MCF7 cells were co-transfected with each of the plasmid constructs shown. Cells were then harvested and 5×10^5 cells were plated in duplicate into complete medium containing G418. Twenty-one to 28 days later, cells were stained and colonies counted. The experiment was repeated four times with similar results. (b) Quantitation of the results from (a)

• *BAP1 is expressed in a temporal and spatial pattern during breast development/remodeling*

The physical interaction between BAP1 and BRCA1 suggests that the proteins might be expressed in similar tissues. Northern blot hybridization analysis of *BAP1* expression in a variety of human adult tissues indicated that human *BAP1* was encoded by a single mRNA species of ~4 kb in all tissues except testis, where a second, ~4.8 kb mRNA, was also detected (Figure 5a). High expression was detected in testis, placenta and ovary, with varying levels detected in the remaining tissues. Expression of *BAP1* in normal human breast tissue was detected by RT-PCR of total RNA isolated from normal human mammary epithelial cells (data not shown).

Northern analysis and *in situ* hybridization were performed to determine whether the spatial and temporal pattern of *Bap1* expression in the breast corresponded to that previously described for *Brcal* (Figure 5b and c; Marquis *et al.*, 1995). *Bap1* was expressed at slightly higher levels in the mammary glands of 5 week-old adolescent female mice compared to 15 week-old mature mice. Consistent with this, *in situ* hybridization revealed high level of *Bap1* mRNA expression in terminal end buds (Figure 5c), and higher levels of *Bap1* expression in the ductal epithelium of adolescent as compared with mature female mice. Like *Brcal*, *Bap1* mRNA was expressed in the mammary epithelium at levels higher than those found in the stromal compartment. Steady-state levels of *Bap1* mRNA were up-regulated in the mammary glands of pregnant mice (Figure 5b and c). Like *Brcal*, *in situ* hybridization demonstrated that this up-regulation occurred predominantly in developing alveoli (Figure 5c). *Bap1* was expressed at higher levels in the mammary glands of parous animals that had undergone 28 days of post-lactational regression as compared with age-matched virgin controls (cf. D28 regression and 15 week virgin). The observation that *Bap1* expression is up-regulated in the breast during puberty, pregnancy and as a result of parity is similar to that previously made for *Brcal* and suggests the developmental co-expression of these two proteins (Marquis *et al.*, 1995). It should be noted, however, that the magnitude of *Bap1* up-regulation at each of these developmental stages was lower than that observed for *Brcal*. The spatial distribution of *Bap1* expression was also investigated in the testis and ovary (Figure 5c). Like *Brcal*, *Bap1* was expressed at high levels in seminiferous tubules, with levels of expression observed in the surrounding connective tissue. *Bap1* was also expressed at high levels throughout the ovary.

BAP1 augments the growth suppressive activity of BRCA1

Several studies have shown that BRCA1 can affect the growth characteristics of cells (Holt *et al.*, 1996; Rao *et al.*, 1996). We determined whether BAP1 itself may affect cell growth or may alter BRCA1-mediated changes in cell growth. *BRCA1* and *BAP1* cDNAs were co-transfected into MCF7 breast cancer cells and analysed for their effect on colony formation (Figure 6). This cell line was chosen for several reasons: First,

Figure 7 *BAP1* maps to Chromosome 3p21.3. Fluorescence *in situ* hybridization (FISH) of partial metaphases using biotin-labeled *BAP1* cDNA. (a) the specific FISH signals on chromosome 3 (arrows), with (b) the simultaneously DAPI-stained chromosomes and (c) a chromosome ideogram with the localization of *BAP1* based on the DAPI-band pattern and FLpter value. The horizontal box indicates the variation in FLpter values on individual chromosomes

it previously has been shown that the growth of these cells is inhibited by the overexpression of *BRCA1* (Holt *et al.*, 1996). Second, both Northern and RT-PCR analyses showed that *BAP1* is expressed in this cell line (data not shown). Finally, RT-PCR/SSCP analysis of the open reading frame of *BAP1* cDNA prepared from this cell line showed no mutations (data not shown).

The expression of *BRCA1* alone (*BRCA1*:pCMV5) decreased the number of colonies formed by these cells when compared to the vector control (pcDNA3:pCMV5), in agreement with other studies (Holt *et al.*, 1996). The co-expression of *BRCA1* and *BAP1* (*BRCA1*:*BAP1*) significantly decreased the number of cell colonies (approximately fourfold vs *BRCA1* alone; see Figure 6b) indicating that *BAP1* enhances the growth suppressive actions of *BRCA1*. A mutant of *BAP1*, *BAP1*(165–729), in which the enzymatic region is deleted but which still binds to *BRCA1*, also enhanced the growth suppression of *BRCA1*, but not to the same extent as the wild-type *BAP1*.

The expression of *BRCA1*-Δ11 (a naturally occurring splice variant of *BRCA1*) in MCF7 cells by itself had no effect on the growth of MCF7 cells (Figure 6).

However, the co-expression of BRCA1-Δ11 and BAP1 dramatically decreased the number of colonies, suggesting that the presence of BAP1 could cooperate with BRCA1-Δ11 in cell growth inhibition. Furthermore, the expression of BAP1 in MCF7 cells also reduced the number of colonies formed (pcDNA3:BAP1; see Figure 6b). The expression of the enzymatic mutant, BAP1(165–729), alone or in combination with BRCA1-Δ11, yielded no growth-suppression activity. Thus, enzymatically active BAP1 enhances BRCA1-mediated suppression of growth in this assay.

BAP1 is located on chromosome 3p21.3 and is mutated in non-small cell lung carcinoma

The data above suggest the possibility that *BAP1* itself may be a tumor suppressor gene and that *BAP1* alterations/deletions might play a role in human tumorigenesis. We determined whether *BAP1* might be located at a chromosomal region previously observed to be mutated in human cancers. The full-

length *BAP1* cDNA was used in fluorescent *in situ* hybridization (FISH) to identify the chromosomal location of the *BAP1* gene (Figure 7). Specific signals were observed only on the midportion of the short arm of chromosome 3 with 42 of 69 analysed metaphase spreads showing at least one specific signal. The FLpter value was 0.27 ± 0.02 corresponding to a localization for *BAP1* at 3p21.2-p21.31. This location is a region of LOH for breast cancer as well as a region frequently deleted in lung carcinomas (Buchhagen *et al.*, 1994; Thiberville *et al.*, 1995).

The chromosomal location of *BAP1* suggested the possibility of mutations within *BAP1* in lung tumors. Thus, a total of 44 small cell lung cancer (SCLC), 33 non-small cell lung cancer (NSCLC) and two lymphoblastoid tumor cell lines were screened for mutations within the *BAP1* gene by Southern, Northern and PCR-based SSCP analyses. Genomic DNAs from 15 small cell lung cancer (SCLC), 18 non-small cell lung cancer (NSCLC) and two lymphoblastoid cell lines (representing a subset of the total), were subjected to *Eco*RI digestion and then hybridized to a full-length

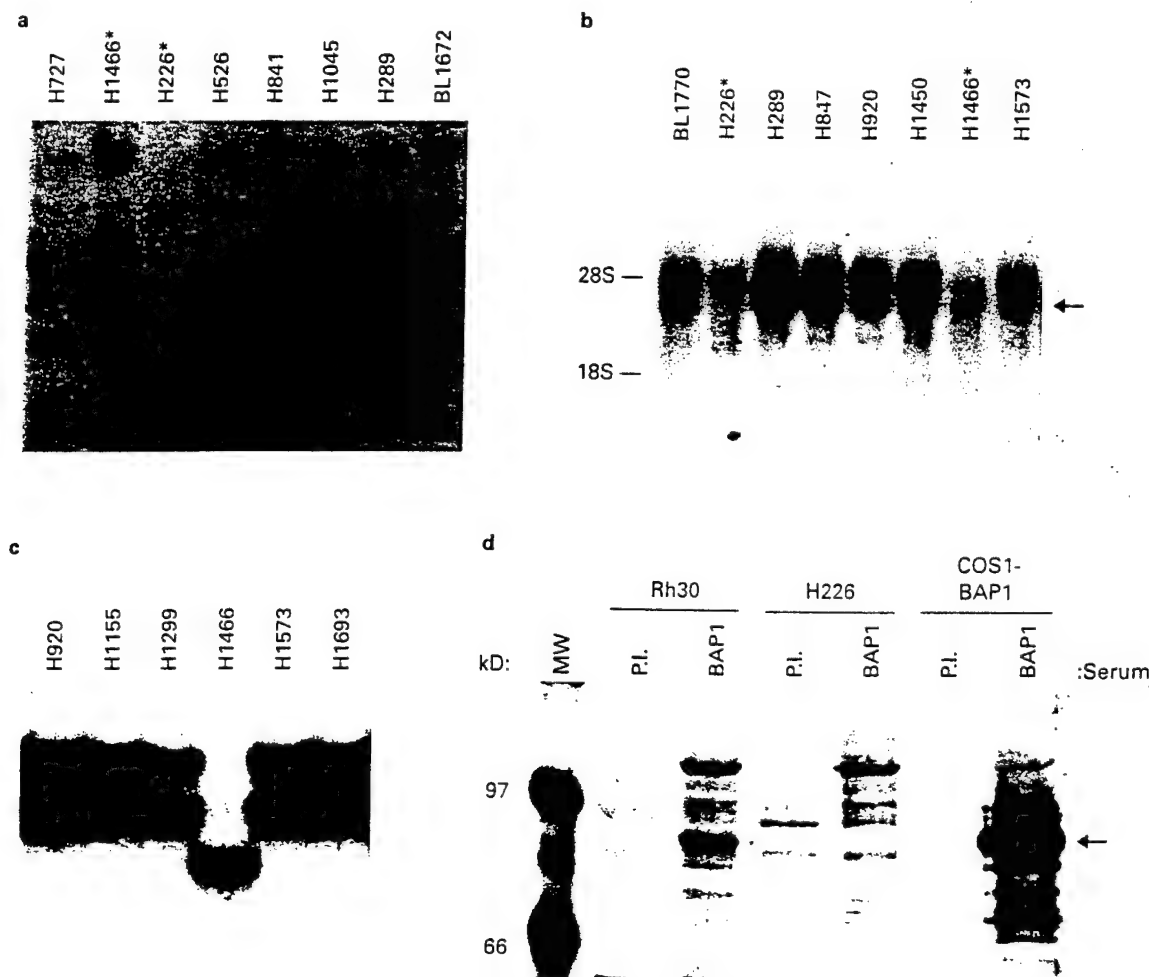

Figure 8 Mutational analysis of lung carcinomas. (a) Southern blot hybridization with *Bam*HI digestion showing four distinct bands at 7.5 kbp, 4.0 kbp, 3.0 kbp and 2.4 kbp as detected by a full-length BAP1 probe. The non-small cell lung cancer NCI-H226 cell line shows an absence of the 7.5 kbp, 4.0 kbp and 3.0 kbp bands. An aberrant 2.6 kbp band is detected in the NCI-H226 cell line. (b) Northern blot hybridization showing a ~4 kb message (arrow) which is absent in the NCI-H226 cell line and the non-small cell lung cancer NCI-H1466 cell line. A fainter (5.0 kb) band is visible corresponding to cross hybridization with the 28S ribosomal component. (c) SSCP analysis showing a homozygous shift in H1466 detected by RT-PCR amplification spanning nts 1089 to 1286. (d) BAP1 is a 90 kD protein and is missing from NCI-H226 cells. Endogenous BAP1 from Rh30 or H226 cells, or BAP1 expressed in COS1 cells from the BAP1 cDNA, was immunoprecipitated from whole cell lysates prepared after ^{35}S -labeling of 1×10^7 cells. Immunoprecipitated proteins were analysed by SDS-PAGE followed by fluorography. The arrow indicates the BAP1 protein. All cell lines in panels a, b and c are listed by their NCI number (Phelps *et al.*, 1996).

BAP1 cDNA probe. A single 23 kb band was detected in the lymphoblastoid and most tumor cell lines (data not shown). One NSCLC line, NCI-H226, did not show the 23 kbp band but did show an aberrant 30 kbp band (data not shown). This abnormality was confirmed by *Bam*HI, *Xba*I, *Pst*I and *Bgl*II digestions. Using the 3.5 kbp BAP1 cDNA probe with *Bam*HI digested genomic DNAs, we detected four distinct bands at 7.5 kbp, 4.0 kbp, 3.0 kbp and 2.4 kbp which were present in all cell lines tested with the exception of NCI-H226 (a representative subset is shown in Figure 8a). In the NCI-H226 line, we detected only the 2.4 kbp band and an aberrant 2.6 kbp band.

Further mutational analysis of BAP1 was performed by screening a subset of 31 SCLC and 27 NSCLC lung cancer cell lines and two lymphoblastoid cell lines for expression of *BAP1* mRNA. Northern analysis showed that most cell lines expressed a single ~4 kb mRNA (Figure 8b). However, two cell lines, NCI-H226 and NCI-H1466 (both NSCLCs), showed undetectable levels of *BAP1* expression, suggesting that *BAP1* may be a target for inactivation or down-regulation during NSCLC pathogenesis. The absence of BAP1 protein in the NCI-H226 line was determined by immunoprecipitation of BAP1 from ³⁵S-labeled cells (Figure 8d).

We screened cDNAs from all 44 SCLC and 33 NSCLC cell lines for mutations in the BAP1 open reading frame by RTPCR-SSCP (Figure 8c). A homozygous, eight base pair deletion and a presumed splice variant were detected. An 8 bp deletion was detected in the cDNA from the NSCLC line NCI-H1466; This short deletion leads to a frameshift/truncation yielding a predicted 393 amino acid protein. This homozygous deletion was confirmed in genomic DNA from the same cell line (data not shown). A 54 bp in-frame deletion (nts. 705–758) was detected in the NCI-H1963 (SCLC) cell line. This deletion was heterozygous at the cDNA level and not present in the genomic DNA, suggesting that it is a splice variant. However, this variant was not detected in any of the other cell lines screened. These data clearly show that genetic alterations, including intra-genic homozygous deletions, can occur in *BAP1*.

Discussion

We have discovered and characterized a novel protein, BAP1, which binds to the BRCA1 RING finger motif. Several lines of evidence are offered which support a role for BAP1 in BRCA1 signal transduction pathways. We showed that: (1) BAP1 binds to the RING finger of BRCA1; but not to germline mutants of BRCA1 or related RING domains; (2) The BAP1–BRCA1 interactions occurs *in vitro* and *in vivo*, and these proteins are partially co-localized in nuclear dot structures; (3) *BAP1* mRNA is expressed in those tissues which also expresses *BRCA1*, and the spatial, temporal distribution of *Bap1* expression in the mouse breast is very similar to that observed with *Brcal*; (4) BAP1 enhances BRCA1-mediated suppression of cell growth in colony formation assays, and suppression by BAP1 is augmented by its UCH enzymatic domain; and (5) *BAP1* maps to chromosome 3p21.3 and is homozygously deleted in a lung carcinoma cell line. Together, these observations suggest that *BAP1* may

be a tumor suppressor gene, and that it may serve as a regulator of (or is an effector for) BRCA1 growth control/differentiation pathways. The specificity of the BRCA1 RING finger-BAP1 interaction and the fact that independent, germline missense mutations in the BRCA1 RING finger domain abolish interaction with BAP1 provide substantial evidence for the physiological relevance of this interaction.

BAP1 is a nuclear-localized, ubiquitin carboxy-terminal hydrolase (UCH) which can cleave model ubiquitin substrates *in vitro*. The UCH homology of BAP1 implies a role for either ubiquitin-mediated, proteasome-dependent degradation or other ubiquitin-mediated regulatory (Isaksson *et al.*, 1996) pathways in BRCA1 function. Regulated ubiquitination of proteins and subsequent proteasome-dependent proteolysis plays a role in almost every cellular growth, differentiation and homeostatic process (reviewed by Ciechanover, 1994; Isaksson *et al.*, 1996; Wilkinson, 1995). The pathway is regulated both at the level of substrate specificity – via the concerted actions of activating enzymes, carrier proteins and ligation enzymes – and at the level of proteolytic deubiquitination and ubiquitin hydrolysis. The latter enzymes are ubiquitin-specific thiol proteases which have been broadly classified into two families: the ubiquitin-specific protease (UBPs) and the ubiquitin carboxy-terminal hydrolases (UCHs).

The UBP family members are 50–300 kDa, cytoplasmic or nuclear-localized proteins which, in general, cleave ubiquitin or ubiquitin-conjugates from large substrates. Such enzymatic activity can be found directly associated with the 26S proteasome and may serve a regulatory function by editing ubiquitin on large substrates or cleaving polyubiquitin, thus replenishing ubiquitin pools (Lam *et al.*, 1997). Remarkably, a number of UBPs have been isolated as growth regulatory and/or developmental control genes such as DOA4 in yeast, which controls DNA replication and repair (Papa and Hochstrasser, 1993); UBP3 which is involved in transcriptional silencing in yeast (Moazed and Johnson, 1996); the TRE2 oncogene which is mutated in the UBP active site and functions as a dominant negative transforming gene (Nakamura *et al.*, 1992); the drosophila *Fat Facets* gene which controls pattern formation and eye development (Huang *et al.*, 1995; Huang and Fischer-Vize, 1996); and the human DUB family of cytokine-inducible UBPs which control hematopoietic differentiation (Zhu *et al.*, 1996, 1997).

By contrast, the UCH family has been characterized as a set of small (25–30 kDa) cytoplasmic proteins which prefer to cleave ubiquitin from ubiquitin-conjugated small substrates and may also be involved in the co-translational processing of proubiquitin. Like the UBPs, UCHs show considerable tissue specificity and developmentally-timed regulation (Wilkinson *et al.*, 1992). UCH family members are differentially expressed in neuronal, hematopoietic and germ cells in many species. Most remarkably, a novel UCH enzyme has recently been cloned from *A. californica* whose enzymatic function is essential for acquisition and maintenance of long-term memory (Hedge *et al.*, 1997). Finally, UCH levels are down-regulated during viral transformation of fibroblasts (Honore *et al.*, 1991), consistent with a role in growth control.

BAP1 is the newest member of the UCH family and considerably expands the potential roles of this family of proteases. BAP1 is a much larger protein (90 kDa) and is the first nuclear-localized UCH. In addition to containing the ~250 amino acid amino-terminal UCH catalytic domain, it includes a carboxy-terminal extension rich in proline, serine and threonine, and a short, highly acidic region; these elements may confer a short half-life upon the protein (Rechsteiner and Rogers, 1996). The extreme carboxy-terminus encodes two potential nuclear localization signals that overlap the approximately 125 amino acid BRCA1-interaction domain. This domain is predicted to fold into a long amphiphatic helix of coiled-coil character, the structure of which may be important for BRCA1 interaction. Indeed, truncation into this region or substitution of a proline for leucine (L691P) abolish the BAP1-BRCA1 interaction in the two-hybrid assay. We have also detected a potential splice variant in BAP1 that results in loss of 31 amino acids of the BRCA1 interaction domain and greatly reduces the ability of BAP1 to bind the BRCA1 RING finger. Thus, our data suggest that the BAP1 carboxy-terminus is tethered to the BRCA1 RING finger domain, leaving the UCH catalytic domain free to interact with ubiquitinated, or other ubiquitin-like, substrates.

A simple model explaining most of our data is that BRCA1 is a direct substrate for the UCH activity of BAP1 and deubiquitination results in the stabilization of BRCA1. Thus, in contrast to the known UCHs which are comprised entirely of the UCH domain, the carboxy-terminal extension of BAP1 may provide substrate and/or targeting specificity for the catalytic function. Paradigms for separate substrate recognition and catalytic domains occur throughout the ubiquitin conjugation/ligation system (see Wilkinson, 1995 and references therein). Regulated ubiquitination of BRCA1 and subsequent proteasome-mediated degradation would be consistent with tight regulation of BRCA1 levels and its subnuclear localization during both the mitotic cell-cycle and meiosis (Gudas *et al.*, 1996; Scully *et al.*, 1997b; Zabludoff *et al.*, 1996). Thus, BAP1-mediated deubiquitination of BRCA1 would stabilize the protein and protect it from proteasome-mediated degradation. This scenario is consistent with both the ability of co-transfected BAP1 to enhance the tumor suppressor effects of BRCA1 in colony formation assays and the finding of mutations in BAP1 in cancer cell lines.

A second, and equally plausible hypothesis is that the BRCA1-BAP1 association serves to target the UCH domain to other substrates that may be bound to other sites on BRCA1. In this scenario, BRCA1 may function as an assembly or scaffold molecule for regulated assembly of multiprotein complexes; a function that has been postulated for other tumor suppressor proteins (e.g. pRb; Sellers and Kaelin, 1996; Welch and Wang, 1995). Thus, BAP1 could be a regulator of this assembly via its control of ubiquitin-mediated proteolysis. Recently, it has been shown that the RING finger protein Ste5 (*S. cerevisiae*) functions as a scaffold protein for assembling protein kinase-dependent signaling complexes in pheromone signaling; this activity is abolished by mutations in the Ste5 RING finger (Inouye *et al.*, 1997). In this context, two other RING finger-containing proteins are involved in

complexes whereby controlled proteolytic processes are dependent upon the integrity of the RING finger structure: (1) The murine homologue of the drosophila *seven-in-absentia*, *siah*, (a RING finger protein) binds to the tumor suppressor protein Deleted in Colon Cancer (DCC) and targets it for proteasome-mediated degradation. This degradation requires the *siah* RING finger structure (Hu *et al.*, 1997); and (2) The herpesvirus protein VMW110 is a RING finger protein that binds directly to a UBP family member, HAUSP, and appears to target it to the ND10/POD nuclear dot structure. The ND10 structure itself contains another RING finger protein, the proto-oncogene PML (Everett *et al.*, 1997). Remarkably, the PML RING finger has been shown to bind and co-localize with a ubiquitin-like molecule PIC1/SUMO1 which is emerging as a central molecule in nuclear-localized ubiquitin-dependent regulation (Saitoh *et al.*, 1997).

A third hypothesis is that BAP1 is involved in the regulation of protein subcellular localization. Mono-ubiquitination, or addition of a ubiquitin-like moiety, has emerged as an important post-translational modification which may affect the specific targeting of proteins to locations other than the proteasome. For example, the addition of the ubiquitin-like PIC1/SUMO1 protein appears to mediate the movement of RanGAP1 (a GTPase-activating protein) from the cytoplasm to the nuclear envelope where it binds the RanBP2 protein (Mahajan *et al.*, 1997). This interaction requires the ATP-dependent, covalent addition of PIC1/SUMO-1 to RanGAP1, a process extremely similar to the ATP-dependent, ubiquitin-ligation mechanism. Thus, BAP1-mediated removal of ubiquitin, or ubiquitin-like molecules, from BRCA1, or a protein associated with BRCA1, could target the complex to another cellular compartment, thus altering its function without physically destroying it. That BRCA1 is targeted to specific subcellular sites is evidenced by the observation that it accumulates in nuclear dot structures during S phase of the cell cycle. This localization is abolished at the S/G2 boundary (Scully *et al.*, 1997b).

The association of BRCA1 with RAD51 in both mitotic nuclear dot structures and meiotic cells broadly implicates BRCA1 in DNA repair and/or recombination processes. The RAD51/52-dependent DNA repair pathway is highly regulated and includes many proteins, some of which may be potential substrates for BAP1-mediated ubiquitin hydrolysis. RAD23, which associates with the RAD51/52 complex, contains an amino-terminal ubiquitin-like domain which is required for RAD23 function and double-strand break repair (Watkins *et al.*, 1993). Recently, a human ubiquitin-like protein, UBL-1, was isolated as a protein which binds directly to the human RAD51/RAD52 complex (Shen *et al.*, 1996b). Interestingly, the yeast homologue of UBL1 is SMT3, which functionally associates with the yeast centromere protein MIF2, a protein required for proper chromosome segregation (Brown, 1995; Brown *et al.*, 1993). Furthermore, the RAD51/52 complex contains a ubiquitin conjugating enzyme, hUBC9/UBE2I (Jiang and Koltin, 1996; Shen *et al.*, 1996a). Thus, it appears that the DNA repair machinery contains both ubiquitin-conjugating and -hydrolyzing

elements, since BAP1 is now implicated as a member of the BRCA1/RAD51/hUBC9 complex. It is possible that BAP1, which is co-expressed with BRCA1 in breast tissue, may regulate the recombination/repair functions of the BRCA1/RAD52 complex by targeting either RAD23 or UBL1 for ubiquitin hydrolysis.

The implications that BAP1 is a key regulator and/or effector of BRCA1 suggest that BAP1 may also play a role in human cancer. The finding that *BAP1* maps to human chromosome 3p21.3 strongly suggested this link: Loss of chromosome 3p genes is a critical event in lung cancer pathogenesis and other carcinomas. Interestingly, two other components of the ubiquitin metabolism pathway have been mapped to chromosome 3p21.3: an ubiquitin activating enzyme (Kok *et al.*, 1993) and a ubiquitin protease, UNP (Gray *et al.*, 1995). The identification of BAP1 as a UCH suggests a cluster of metabolically related enzymes at this locus. Furthermore, the frequent loss of this chromosomal region suggests that there may be a selective advantage for the loss of ubiquitin-mediated cellular processes during carcinogenesis. That BAP1 may be included in this paradigm is suggested by our detection of rearrangements/deletions within BAP1 in lung cancers (this report) and our detection of independent, homozygous, point mutations in highly conserved residues of BAP1's enzymatic domain (Proctor *et al.*, manuscript in preparation).

In summary, we have isolated a novel ubiquitin hydrolase which associates directly with the BRCA1 RING finger domain. BAP1 may play a key role in ubiquitin-dependent regulatory processes in the nucleus including transcription, chromatin remodeling, cell cycle control and DNA repair/recombination.

Materials and methods

Cell culture, transfections and colony formation assays

All cells were grown at 37°C and 5% CO₂. COS1 and MCF7 cells were maintained in DMEM supplemented with 10% fetal bovine serum (FBS), L-glutamine and non-essential amino acids. Small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC) cell lines were maintained in RPMI media with 10% fetal bovine serum (Gibco BRL). Rh30 cells were maintained in RPMI supplemented with 10% FBS and non-essential amino acids. COS1 cells were transfected using DOPOR transfection reagent (Boehringer Mannheim Biochemicals) following the manufacturer's protocol.

Colony formation assay

MCF7 cells were transfected by a modified CaPO₄-DNA precipitation method (Holt *et al.*, 1996). MCF7 cells, at 2 × 10⁶ cells/10 cm dish, were fed fresh medium approximately 3 h prior to transfection, and were then treated with the Ca-DNA precipitate for 4 h. The cells were subjected to a brief shock with transfection buffer containing 15% glycerol. Twelve to 16 h later, the cells were trypsinized, counted and plated directly into complete medium containing 0.75 mg/mL G418 at 5 × 10⁵ cells per 10 cm dish. Cells were fed fresh medium containing G418 every 3–4 days. Cells were stained for colonies approximately 21–28 days after transfection.

Yeast 2-hybrid

The yeast 2-hybrid system as modified by Stan Hollenberg was used for all yeast experiments (Vojtek *et al.*, 1993). Two libraries were screened for interaction with LexA-BRCA1: a human B cell, oligo-dT-primed, cDNA library (Durfee *et al.*, 1993); a kind gift from Dr Steve Elledge) and a mouse embryo (9.5–10.5 day), random-primed, cDNA library size selected for inserts of 300–500 base pairs in length (Vojtek *et al.*, 1993); a kind gift of Dr Stan Hollenberg).

Construction of expression plasmids

LexA fusion constructs: The 100 amino acid terminal region of human BRCA1 (BRCA1-RF) was used as the bait to screen for interacting proteins. All LexA fusion constructs were made by cloning the appropriate RING (or other) domain into the vector pBTM-116 (Vojtek *et al.*, 1993). A synthetic gene of the BRCA1-RF domain was made from overlapping oligonucleotides whose codon usage had been optimized for expression in *E. coli* and *S. cerevisiae* (Madden *et al.*, 1991). Double-stranded DNA was generated by the Polymerase Chain Reaction (PCR) and amplified with flanking primers containing *Eco*RI and *Sal*I enzymatic restriction sites. A 'wild type' BRCA1-RF domain was confirmed by DNA sequencing. The single amino acid substitutions in the BRCA1-RF domain, BRCA1(C64G) (Cys 64 to Gly), BRCA1(C61G) (Cys 61 to Gly), BRCA1(M18T) (Met18Thr) and BRCA1(R71G) (Arg71 to Gly) as well as the BRCA1-delAG185 truncation mutant were created by PCR-mutagenesis (Ho *et al.*, 1989). The BRCA1-del31 truncation mutant was a mis-primed PCR reaction of the BRCA1-RF which was identified by DNA sequencing. The LexA-RPT-1 protein (amino acids 1–100) was made by PCR-mediated amplification of the corresponding nucleotides of a RPT-1 PCR sample (Patarca *et al.*, 1988); kindly provided by Dr Harvey Cantor). All clones were confirmed by sequencing. Expression of all constructs in yeast was confirmed by Western analysis using antibodies against the LexA DNA-binding domain (data not shown).

BAP1 constructs: A full-length BAP1 cDNA was assembled through the fusion of two overlapping EST clones (the IMAGE Consortium (LLNL); cDNA Clones #46154 and #40642; (Lennon *et al.*, 1996)) and the insertion of 62 nucleotides missing from clone #40642 (as revealed by sequencing and RT-PCR analyses). GST-hBAP1(483–729) was generated by cloning the *Xho*I fragment of pAct (the original human two-hybrid clone; nucleotides 1486–3525) into pGEX-5x-1 (Pharmacia Biotech, Inc.). GST-hBAP1(438–594) and pACT-hBAP1(438–594) (nucleotides 1486–1821) were generated and amplified by PCR, digested with restriction enzyme and ligated into the appropriate vector.

Mapping of BRCA1-BAP1 interaction domain

Truncations of mBAP(596–721), and the point mutation mBAP1(L691P), were generated by PCR-based mutagenesis. Products were then ligated into the mouse library-yeast expression vector, pVP16. All clones were confirmed by sequencing and expression in yeast was confirmed by Western analysis using antibodies against the VP16 activation domain (data not shown).

Northern and in situ

Tissue RNA blots were obtained from Clontech Laboratories, Inc. (Palo Alto, CA). Blots were hybridized with ³²P-labeled hBAP1(483–729) cDNA (nucleotides 1486–3525) using standard protocols. RNA

preparation. Northern hybridization of mouse mammary tissue, and *in situ* hybridization analyses were performed as previously described using the mouse Bap1 cDNA probe described by mBAP1(596–721), corresponding to nucleotides 1825–2202 of the human probe (Marquis *et al.*, 1995).

Fluorescent *in situ* hybridization (FISH)

FISH using a biotin-labeled 3.5 kb cDNA (full length) clone of BAP1, with corresponding DAPI-banding and measurement of the relative distance from the short arm telomere to the signals (FLpter value) was performed as described previously (Tommerup and Vissing, 1995).

Immunolocalization

All immunofluorescence was performed as previously described (Ishov and Maul, 1996). BAP1 protein was detected with affinity purified, BAP1-specific polyclonal antibodies, and BRCA1 was detected with the BR64 monoclonal antibody (Upstate Biotechnology), which were detected with FITC and Texas Red (respectively) using biotin-avidin enhancement. Cells were stained for DNA with bis-benzimide (Hoescht 33258, Sigma Chemical Co.) and mounted using Fluoromount G (Fisher Scientific). Analysis was performed with a confocal scanning microscope (Leica, Inc.).

BAP1 protein characterization

Generation of antibodies: Using PCR cloning, the cDNA region encoding amino acids 483–576 of BAP1 was fused downstream of the six Histidine residues of the vector pQE-30 (QIAGEN Inc.). The His-tagged protein was purified from *E. coli* over a Ni-agarose column as previously described (Friedman *et al.*, 1996) and was used to immunize rabbits for the production of polyclonal antibodies (Cocalico Biologicals, Inc.). Immunoprecipitation of BAP1 was performed by previously described procedures for the metabolic labeling and immunoprecipitation of proteins from cell lysates (Friedman *et al.*, 1996).

In vitro protein association: GST, GST-hBAP1(483–729) and GST-hBAP1(483–594) were expressed in *E. coli* and then purified as described (Frangioni and Neel, 1993). The ³⁵S-BRCA1 protein was produced *in vitro* via coupled transcription/translation (TNT[®], Promega Corp.). Association between proteins was assayed as described previously (Barlev *et al.*, 1995).

BAP1 enzymatic assay

Assays for BAP1 enzymatic activity were performed essentially as described for the UCH-L1 and UCH-L3 enzymes (Mayer and Wilkinson, 1989). Briefly, bacteria harboring an IPTG-inducible expression plasmid containing BAP1 (pQE-30; QIAGEN Inc.) were grown and induced with 1 mM IPTG for 4 h. The bacteria were collected and the pellets were resuspended to 1:20 volume (original culture) in lysate buffer (50 mM Tris, pH 8.0, 25 mM EDTA, 10 mM 2-mercapto-ethanol, 100 µg/ml lysozyme). The lysates were sonicated and centrifuged at 40 000 g. The soluble fractions were used for subsequent activity assays. The pellets were resuspended in a volume equal to that of the supernatant and samples of both pellet and supernatant were analysed by SDS-PAGE for expression levels and inclusion body formation.

Assays for ubiquitin carboxy-terminal hydrolase activity were performed using the glycine 76 ethyl ester of ubiquitin (Ub-OEt) as substrate (Mayer and Wilkinson, 1989; Wilkinson *et al.*, 1986). Assays were done in triplicate. The

peak areas were integrated and normalized with respect to a ubiquitin standard.

Mutation screening

RNA/DNA preparation: Genomic DNA was prepared from breast and lung cancer cell lines using standard methods. Total RNA was extracted by the cesium chloride-ultracentrifugation method (Ausubel *et al.*, 1987). First strand cDNAs were synthesized from RNA by M-MLV reverse transcriptase (Gibco-BRL) according to the manufacturer's instructions.

Southern and Northern blot hybridization: Five µg of genomic DNA, subjected to restriction enzyme digestion, or 10 µg total RNA, was electrophoretically gel-fractionated and transferred to Hybond N⁺ membranes (Amersham). Hybridization was performed with a ³²P-full-length BAP1 cDNA probe followed by washes under standard conditions and detection by autoradiography.

Single strand conformational polymorphism (SSCP) analysis: Seventeen overlapping PCR primer pairs, each with a predicted product size of approximately 200 base pairs, were designed to span the 2.2 kb open reading frame of the BAP1 cDNA sequence. cDNA (from RNA) was amplified in 20 µl PCR reactions containing 20 mM Tris HCl (pH 8.3), 50 mM KCl, 1.5 mM MgCl₂, 0.2 mM each dNTP, 0.1 mM each forward and reverse primer, 0.05 ml [³²P]-αdCTP and 0.5 units Taq DNA Polymerase (BRL). PCR reactions were carried out in a Perkin-Elmer 9600 Thermocycler using a touchdown technique: a 2.5 min initial denaturation at 94°C was followed by 35 cycles of denaturation at 94°C × 30 s, annealing, initially at 65°C decreasing by 1°C for each of the first ten cycles to 55°C, × 30 s, and extension at 72°C × 30 s with a final extension of 5 min at 72°C. PCR products were then diluted 1:10 with SSCP dye (95% formamide, 20 mM EDTA, and 0.05% each of bromophenol blue and xylene cyanol), heat-denatured, and electrophoresed on 0.5 × MDE gels ± 10% glycerol. Abnormal single stranded DNA detected as autoradiographic shifts were re-amplified by PCR and subjected to automated dye-terminator sequencing (ABI 373).

Acknowledgements

We thank E Koonin (NIH/NCBI) for DNA sequence analysis and suggesting a potential gap in our original cDNA clone; Dr R Baer for supplying an anti-BAP1 antibody which allowed us to verify a variety of results; Drs B Weber, F Couch, W Fredericks and J Friedman for their many helpful discussions and the technical assistance of Jing Wang, Bodil Olsen and Winni Pedersen. Nuclear Redistribution of BRCA1 during Viral Infection¹

Abstract

The functions and the intracellular localization of the breast/ovarian susceptibility gene product, BRCA1, has been controversial. To arrive at a clear understanding of its localization and relative position to other nuclear structures, a new monoclonal antibody was produced and characterized by immunohistochemical techniques with other BRCA1 antibodies. Each of the antibodies specifically detected BRCA1 as localized to specific nuclear domains and did so in a variety of cells and in a cell cycle-dependent manner. However, all antibodies also cross-reacted with the centrosomal domain, suggesting that BRCA1 is also localized to this important mitotic component. We found that the BRCA1-containing nuclear domains are different than any of the well-defined nuclear domains. However, a cell cycle-related partial overlap was found for HP1 α , a chromo-domain-containing protein involved in heterochromatin maintenance. Cellular stimuli, such as heat shock and herpes virus infection, dispersed BRCA1 from its domains. In contrast, infection with adenovirus 5 recruited BRCA1 to regions of viral transcription and replication. These disparate distributions of BRCA1 may provide clues to its function.

Introduction

The identification of the breast cancer susceptibility gene *BRCA1* (1) has triggered an intensive search for its function. Much of this search has focused on the identification of interacting proteins and has yielded components of the nuclear import pathway (2) and a novel RING finger-containing protein BARD1 (3, 4). Recently, we identified the BRCA1-associated protein BAP1 (5), which is a nuclear localized ubiquitin hydrolase, suggesting that BRCA1 functions may be either mediated or regulated through ubiquitin-related

modifications. BRCA1 also seems to be associated with the DNA recombination/repair protein RAD51 in meiotic cells (6), suggesting involvement of BRCA1 in the fidelity of DNA replication. Biological clues to the function(s) of BRCA1 have come through over- or underexpression studies. A reduction in BRCA1 availability by antisense expression yielded transformed fibroblasts and accelerated growth of breast cancer cell lines (7, 8), whereas overexpression of wild-type BRCA1 inhibited colony formation and tumor growth *in vivo* (9). These observations are consistent with the genetic evidence that BRCA1 functions as a tumor suppressor (5, 9).

The *BRCA1* gene encodes an 1863 amino acid protein of M_r ~220,000, which is predominately found within the nucleus (4, 10), although some investigators have observed cytoplasmic localization (11, 12). The BRCA1 protein contains two highly conserved regions, one at the NH₂ terminus and the other at the COOH terminus. The COOH terminus contains an acidic region and two copies of a novel motif, designated the BRCT domain. The BRCT domain is present in a variety of putative cell cycle-related proteins, including RAD9 and 53BP1 (13), as well as the BRCA1-associated protein BARD1 (3). The BRCA1 COOH-terminal domain is capable of activating transcription as a Gal4 DNA-binding domain fusion (14), suggesting a role for BRCA1 in transcriptional regulation. The cofractionation of BRCA1 with the RNA pol II holoenzyme (15) supports this hypothesis. However, not all of the cellular BRCA1 cofractionates with pol II, suggesting multiple functions for BRCA1.

The NH₂-terminal region is a 100-amino acid sequence encoding a RING finger domain, which is predicted to bind zinc (16, 17). This motif is defined by a spatially conserved set of cysteine-histidine residues of the form C3HC4 (reviewed in Refs. 18 and 19). The RING motif occurs in >80 proteins, including the products of proto-oncogenes and putative transcription factors (19), and most likely functions as a protein-protein interface. Evidence for this hypothesis has come from the study of the proto-oncogene *PML* (16), the transcriptional corepressor KAP-1 (20), and a ubiquitin hydrolase, BAP1 (5).

The abundance and intracellular location of BRCA1 varies with the cell cycle. BRCA1 protein levels are low in G₁ and reach a maximum during S phase, results that are consistent with BRCA1 RNA expression patterns (21-24). Interestingly, the location of BRCA1 within the nucleus seems to vary with the cell cycle. BRCA1 is detected as diffuse immunofluorescent staining throughout the nucleus during G₁, but then localizes to discrete nuclear domains during S phase (4, 10). The functional effects of these cellular and biochemical changes remain unknown.

The nucleus is a highly organized structure, not only in the positioning of chromosomes in specific territories, but also by the distribution of extrachromosomal domains, e.g., the interchromatinic granules recognizable by the location of the spliceosome assembly factor SC35 (25, 26). In addition,

coiled bodies were found to be associated with specific genes and snRNA and associated proteins (27–30). PIKA is a nuclear domain that shows cell cycle-associated changes in the aggregation of HP-1 (31). Other specifically circumscribed nuclear domains (ND10) have been described to contain the proto-oncogene product PML as well as Int-6, which, if interrupted in the mouse by a retrovirus, results in mammary tumors (32, 33). Although the biochemical functions of these domains are not known, various nuclear processes, such as RNA processing (SC35 domain) and initiation of DNA virus replication and transcription (34, 35), occur at these domains. Because BRCA1 is also localized to discrete nuclear domains, potential functions of BRCA1 may be suggested, or excluded, by interaction or colocalization with any of the known nuclear domains. The relative position of BRCA1 in the nucleus may therefore be informative.

Recent findings on nuclear structure and distribution of specific proteins after viral infection showed that some of these proteins are modified at specific stages of viral infection. Most instructive are those proteins that appear at very early times of the viral reproductive cycle before nuclear damage becomes apparent and which can be traced to the activity of a specific immediate-early protein. The IE1 gene product of HSV³ type 1 disperses the ND10-associated proteins (36–38), and the E4orf3 gene product of Ad5 repositions the same proteins into short tracks (39–41). We therefore used these viruses to determine whether they have any effect on BRCA1 distribution.

The ability to establish colocalization of two proteins by microscopic examination suggested that this methodology could be used as a means to search for other correlations of either the nuclear sites with known functions or for conditions that change the distribution of BRCA1. We therefore developed a MAb that reliably localized BRCA1 relative to different nuclear domains. The results of these experiments clearly show that BRCA1 is a protein with dramatic nuclear repositioning during the cell cycle and upon experimental manipulations of the cell such as stress and viral infection. These changes suggest that Ad5 transcription and replication can provide the experimental system to help elucidate BRCA1 functions.

Results

Characterization of MAb BR64. To determine possible functions for BRCA1, we investigated its subcellular localization and its potential colocalization with a variety of known nuclear proteins of differing function. Investigation of the subcellular localization of BRCA1 required a well-characterized, highly specific antibody. Toward this end, we developed a MAb specific for BRCA1, using the first 100 amino acids of the BRCA1 protein as the antigen (Fig. 1A). This region was expressed in *Escherichia coli* as a histidine fusion protein, purified under denaturing conditions and renatured by dialysis (see "Materials and Methods" and Ref. 20). This

purified protein was used as the immunizing agent in mice, and MAbs were produced using standard technology.

Because the immunizing antigen contains the RING finger domain of BRCA1 and because many proteins contain RING domains, we determined the specificity of our MAb, termed BR64, for the BRCA1 RING domain *versus* the RING domains of two other, unrelated proteins; the transcriptional corepressor KAP-1 and the immediate-early protein ICP0, from HSV type I. Through immunoprecipitation analyses with the BR64 antibody, we found that it detected the BRCA1 RING domain in both the full-length protein and the smaller BRCA1- Δ 11 protein (an alternatively spliced version of BRCA1; Ref. 42) but not either of the other RING domains (Fig. 2A), suggesting that the antibody identifies a sequence-specific region of BRCA1 rather than a structural component of the RING finger, which may be in common with other RING domains.

Mutations occur throughout BRCA1, and most are truncations or nonsense mutations (43). Given that the epitope of this antibody is at the NH₂ terminus of the protein, it should detect all except the shortest BRCA1 mutant proteins. Therefore, we characterized whether BR64 could identify BRCA1 protein that contained any one of several mutations identified previously in breast cancer kindreds, focusing on mutations found in the RING domain (Fig. 1B). We used proteins that contained the LexA DNA binding domain fused to: (a) the first 100 amino acids of BRCA1 (BRCA1-RF); (b) this same region but containing a missense mutation in a metal-coordinating cysteine residue [BRCA1-RF(C61G) and BRCA1-RF(C64G)]; or (c) a truncated BRCA1-RF containing the appropriate number of amino acids as dictated by the mutation (delAG185, 29 amino acids; del31, 31 amino acids). The RING domain of the T-cell transcription factor RPT-1 (44), the most closely related RING finger sequence, was also included. Again, immunoprecipitation analysis was used to identify proteins bound by the BR64 antibody (Fig. 2B). The BR64 antibody identified only those proteins that contained the full RING domain region, regardless of the presence or absence of missense mutations (Fig. 2B). Again, these results suggest that the BR64 antibody identifies a sequence-specific region of BRCA1, rather than a structural component of the RING finger, because the missense mutations are predicted to abolish the coordination of one of the zinc atoms leading to the disruption of the complex RING structure (16). The fact that the RING domain of the RPT-1 protein was not identified by BR64 further suggests that the antibody identifies a sequence-specific domain within BRCA1. The proteins fused to the LexA DNA-binding domain always appeared as doublet bands on SDS-PAGE. This was true for the LexA DNA-binding domain alone as well (data not shown) and is presumably due to an alternate, in-frame, translation start site within the LexA cDNA.

We determined the subregion within the NH₂ terminal 100 amino acids of BRCA1 that the BR64 MAb detects. LexA-BRCA1-RF fusion proteins, containing successive 10-amino acid deletions from the COOH terminus of the 100-amino acid BRCA1 RING finger protein, were immunoprecipitated with the BR64 MAb (Fig. 1B and Fig. 2C). The BR64 MAb detected the full-length RING finger domain [BRCA1 (1–100)]

A.**B.**

Fig. 1. *A*, diagrammatic representation of the BRCA1 protein and the RING finger domain used to generate the 6XHis-BRCA1-RF fusion protein. The identified fusion protein was produced in bacteria, purified by nickel-NTA chromatography (Qiagen, Inc.), and analyzed by SDS-PAGE for purity. Shown is a photograph of the Coomassie blue-stained gel. In *B*, the NH₂-terminal 100 amino acids of human BRCA1 (including the RING finger domain) or the indicated amino acids of the various BRCA1-RF mutants, deletions, and controls were fused to the LexA DNA-binding domain. These constructs were then used to produce the fusion protein by coupled *in vitro* transcription and translation. These proteins were used without further purification in immunoprecipitation analyses with the BR64 MAb. A summary of the results shown in Fig. 2 is shown to the right of the diagrams.

and the RING domain truncated by 10 amino acids [BRCA1 (1-90)]. The 20- and 30-amino acid deletions, BRCA1 (1-80) and BRCA1 (1-70), were not detected by BR64, clearly indicating that amino acids 80-100 contain the region identified by BR64. Indeed, preincubation of the BR64 antibody with a 14-amino acid peptide (amino acids 81-94; H-KKK-QLVEELLKIIICAFQ-KK-OH) inhibited the detection of BRCA1 by immunofluorescence analysis (data not shown). These

analyses suggest that the BR64 antibody detects an epitope COOH-terminal to the C3HC4 motif, which defines the RING domain proper.

The ability of BR64 to detect authentic, endogenous BRCA1 protein was determined through three methodologies; immunoprecipitation; immunoprecipitation followed by Western blot analysis; and direct Western blot analysis of nuclear extract. That BR64 detected BRCA1 was determined

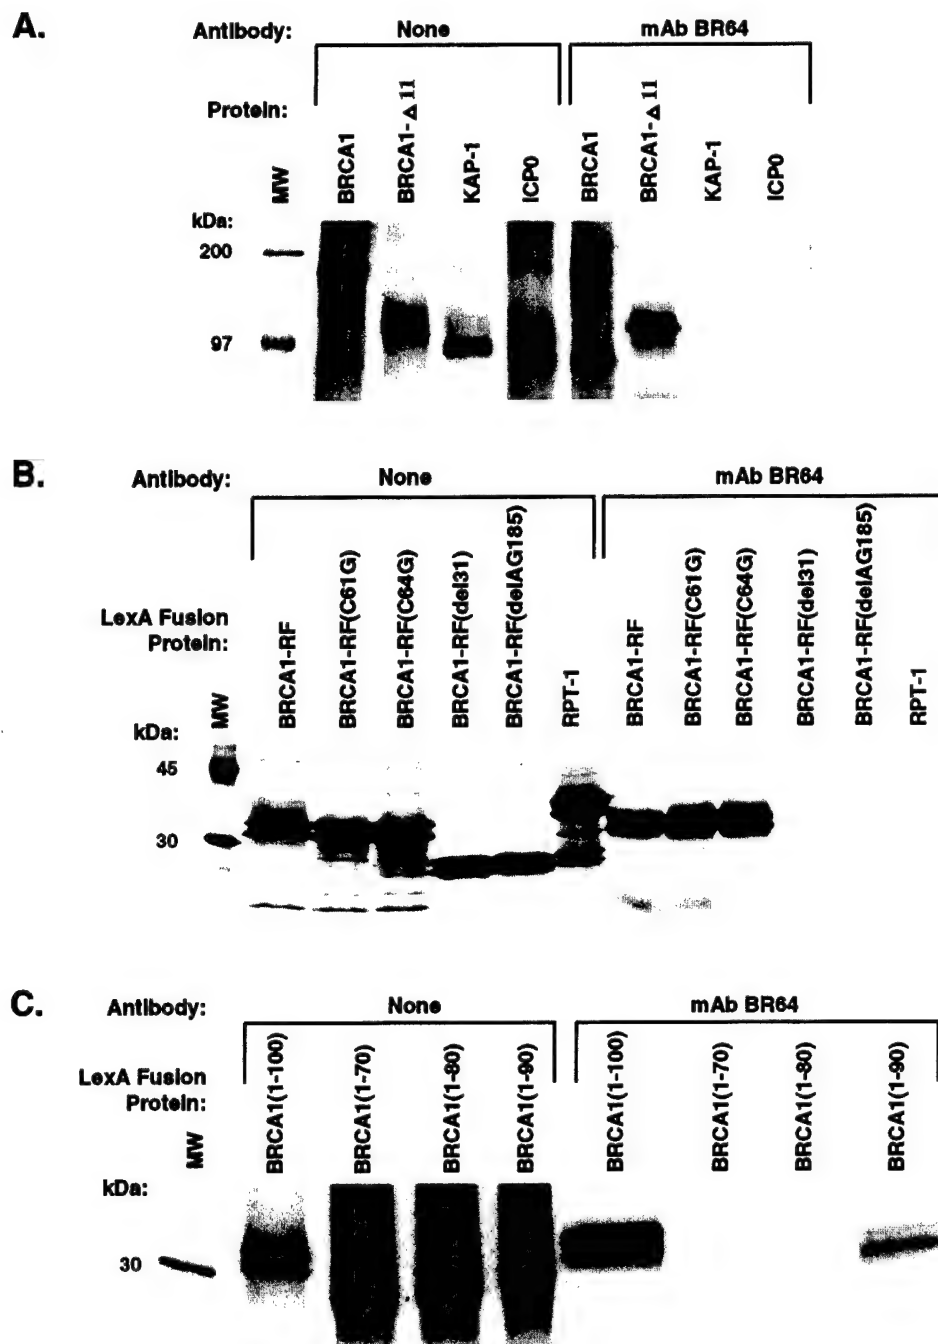

Fig. 2. In A, the BR64 MAb detects only the BRCA1 RING finger domain. The indicated RING finger-containing proteins were transcribed and translated *in vitro* in the presence of [³⁵S]methionine. They were then immunoprecipitated with the BR64 MAb, and the bound proteins were separated by SDS-PAGE. Proteins were then detected by fluorography. Faster-migrating proteins detected by the BR64 MAb in the BRCA1 lane are most likely proteolytic fragments of BRCA1. The appearance and intensity of these proteins varied with each *in vitro* transcription-translation reaction. In B, BRCA1 RING finger domains containing missense mutations can be detected by BR64. Mutations found in breast cancer kindreds were introduced into LexA-BRCA1-RF fusion proteins. These proteins were transcribed and translated *in vitro* in the presence of [³⁵S]methionine, followed by immunoprecipitation with the BR64 MAb. Bound proteins were separated by SDS-PAGE and detected by fluorography. LexA-RPT-1 is a fusion protein containing the RING finger domain from the RPT-1 protein. In C, amino acids 80–100 of the BRCA1 protein contain the epitope for the BR64 MAb. Truncated LexA-BRCA1-RF fusion proteins were transcribed and translated *in vitro* in the presence of [³⁵S]methionine and then immunoprecipitated with the BR64 MAb. Bound proteins were detected by fluorography after separation by SDS-PAGE. Proteins fused to the LexA DNA-binding domain always appear as doublet bands on SDS-PAGE. This is true for the LexA DNA-binding domain alone as well (data not shown) and is presumably due to an alternate, in-frame, translation start site within the LexA cDNA.

by a comparison of the products immunoprecipitated from whole-cell extracts of ³²PO₄-labeled MDA-468 breast cancer cells by the BR64 MAb and the commercially available C20 polyclonal antibody (Fig. 3A). Both antibodies identify a M_r 220,000 phosphoprotein, suggesting that the protein detected by BR64 is BRCA1. Furthermore, BRCA1 is the only phosphoprotein detected by BR64, whereas the C20 antibody detects three other phosphoproteins of M_r 190,000, M_r 97,000, and M_r 70,000.

A second piece of evidence that the endogenous protein detected by BR64 is BRCA1 was obtained via immunopre-

cipitation-Western analysis (Fig. 3B). Whole-cell extracts prepared from HBL100 breast cancer cells were immunoprecipitated with either (rabbit) preimmune serum or anti-BRCA1 immune serum. The immunoprecipitated proteins were then analyzed by Western blot. The BR64 MAb detected a protein of M_r 220,000 previously immunoprecipitated by a specific anti-BRCA1 antibody. However, BR64 also detected a second, faster migrating protein. To address the possibility that BR64 interacted with another protein of large molecular weight, direct Western analysis of nuclear extract from HeLa cells was performed (Fig. 3C). The BR64

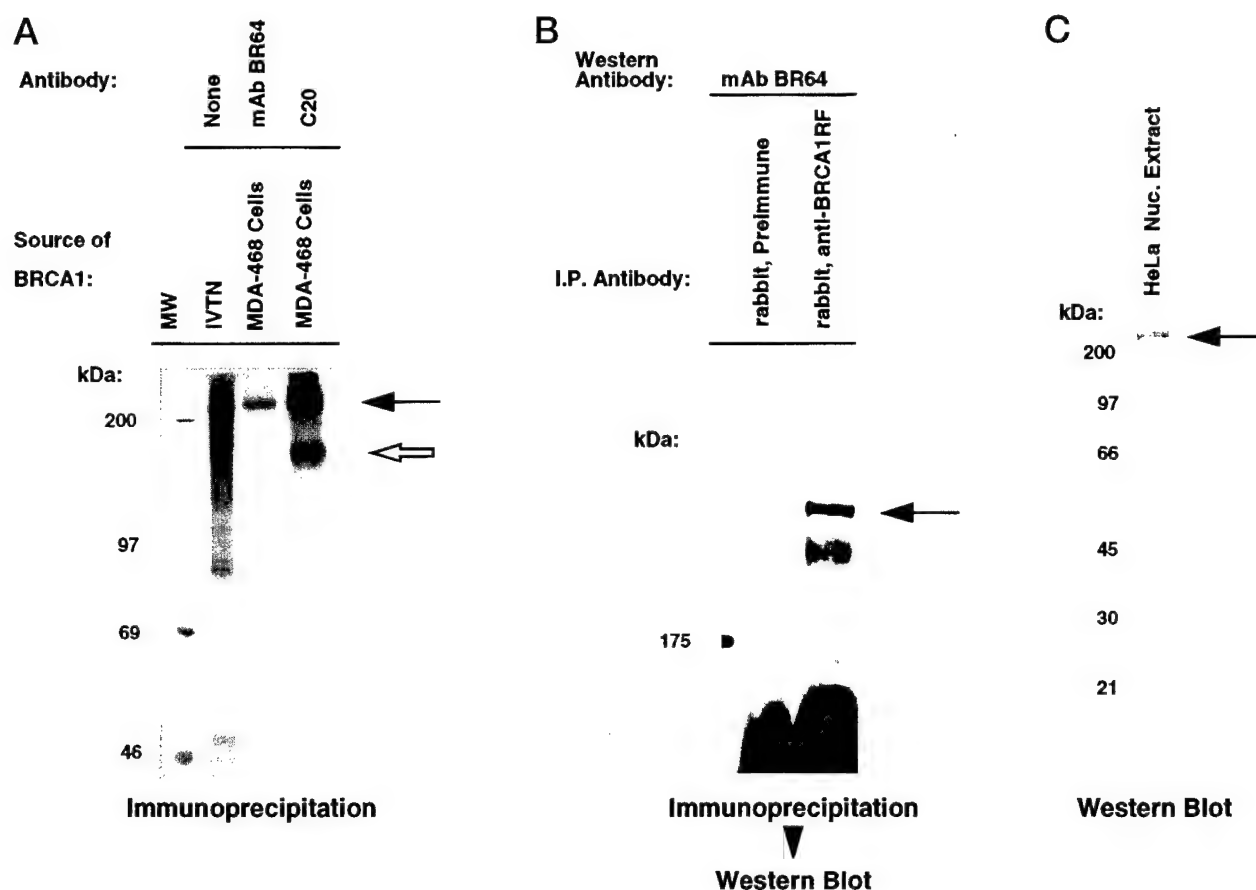

Fig. 3. BR64 detects endogenous BRCA1 protein. In **A**, whole-cell extracts from $^{32}\text{PO}_4$ -labeled MDA-468 breast cancer cells ($5\text{--}7 \times 10^6$ cells) were immunoprecipitated with the BR64 MAb or the C-20 polyclonal antibody. A BRCA1 cDNA was transcribed and translated *in vitro* in the presence of [^{35}S]methionine to produce protein for size comparison purposes. Proteins were separated by SDS-PAGE and detected by fluorography. In **B**, whole-cell extracts from the breast cancer cell line HBL-100 ($1\text{--}2 \times 10^6$ cells) were immunoprecipitated with preimmune sera or with anti-BRCA1-RF polyclonal antibodies. The immunoprecipitated proteins were separated by SDS-PAGE and transferred to a polyvinylidene difluoride membrane. The membrane was immunoblotted with the BR64 MAb and detected with HRP-conjugated goat anti-mouse IgG. In **C**, nuclear extract from HeLa cells was separated by SDS-PAGE and transferred to a polyvinylidene difluoride membrane. The membrane was immunoblotted with the BR64 MAb and detected with alkaline phosphatase-conjugated goat anti-mouse IgG.

MAb detected only a single protein of M_r 220,000, the size of BRCA1. Taken together, these results show that BR64 identifies only the BRCA1 protein, can identify native and denatured BRCA1 protein, and has an epitope defined by amino acids 80–100. The faster migrating protein of Fig. 3B remains unidentified and is not seen in the immunoprecipitation-Western blot analysis when other anti-BRCA1 antibodies are used (data not shown).

Comparison of Different BRCA1 Antibodies. Initial reports that BRCA1 was localized to the cell membrane and the Golgi apparatus and was perhaps secreted (12) have generated significant controversy. It was therefore essential to test whether the earlier reports could be confirmed with different MAbs. When the BR64 MAb was tested by immunohistochemical methods, it reacted nearly exclusively with proteins in the nucleus. However, not all cells showed the same distribution as reported previously by others (10). Nuclei of some cells displayed a sandy fluorescence where as others had, in addition, distinctly higher aggregations of the antigen (Fig. 4A). There was a faint background staining over

the cytoplasm, and often two dots were recognized at the position of the centrosome (Fig. 4A, arrow). Another anti-BRCA1 MAb, M13 (see "Materials and Methods"), recognized the same nuclear patterns (HEp-2 cells) with slightly elevated cytoplasmic staining. In a few cells, particularly mitotic cells, M13 detected numerous cytoplasmic dots over a strong cytoplasmic background (Fig. 4B). A third anti-BRCA1 MAb, 17F8 (see "Materials and Methods"), labeled a large number of cytoplasmic dots in all cells. Nuclear staining by this MAb was difficult to distinguish from the cytoplasmic staining, but it appears similar to that of the other two MAbs. In addition, each cell stained by 17F8 contained an area of strong staining that localized to the centromeric region and appeared at times to overlap with the nucleus when imaged in the same optical section (Fig. 4C, arrows; optical sections are $\sim 0.7\text{-}\mu\text{m}$ thick). A rabbit antibody (C20; Santa Cruz), raised against the COOH-terminal 20 amino acids of BRCA1, labeled the same nuclear components as all three MAbs (Fig. 4D) but also stained the Flemming body (data not shown) and, in a few cells, a limited number of cytoplasmic granules.

Fig. 4. Characterization of BRCA1 distribution in different cells and relative to different nuclear domains by immunofluorescence microscopy. The color is given for each of the different antigens in the *upper corners* of each individual image. **A**, MAb BR64-labeled HEp-2; *arrows* point to cytoplasmic double dots representing the centrosome. **B**, MAb M13-labeled HEp-2 cells. **C**, MAb 17F8-labeled HEp-2 cells. **D**, polyclonal antibody C-20-labeled HEp-2 cells. **E**, MAb BR64-labeled MDA-MB-468 cells; *arrows* point to the centrosome. **F**, MAb M13-labeled MDA-MB-468 cells showing dominant fibrillar cytoplasmic staining. **G**, MAb 17F8-labeled MDA-MB-468 cells showing strong staining of cytoplasmic granules. **H**, double labeled HEp-2 cells using polyclonal antibody C-20 and BR64 showing complete overlap. **I**, double labeled HBL-100 cells using MAb BR64 and human anti-centromere antibodies to show in the upper half daughter cells in early G₁ phase and larger daughter cells with aggregated centromeres. **J**, same as **I** but showing a G₁-phase cell at a later time after mitosis and two larger cells with aggregated centromeres suggestive of S-phase cells. **K**, same staining as **I** having two large cells with centromeres that are often present as doublets suggestive of G₂-phase cells. All optical sections are ~0.7 μm thick.

That the new MAb BR64 recognizes the same nuclear structures as C20 is shown by double labeling (Fig. 4H). The BRCA1 distribution detected in HEp-2 cells by these antibodies was also found in the diploid human fibroblast cell line WI38 and the breast cancer cell line HBL100 (data not shown). The different antibodies, therefore, recognize the same structural components in the nucleus but appear to have individual, minor, cross-reactivities. We conclude that, in general, the sandy nuclear staining of some cells and the specific nuclear domain dot-like staining of other cells is similar for all of the antibodies and is therefore considered specific for the location of BRCA1.

Quite different images were prevalent when testing these four antibodies on the breast cancer cell line MDA-MB-468. Only a very small number of these breast cancer cells had any particulate, nuclear BRCA1 staining, although the images presented were selected to contain one nucleus with such staining to show that this distribution can exist in this cell type. BR64, of the four antibodies tested, revealed the same image as expected from the Hep-2 cells (Fig. 4E, arrows point to centrosomes). MAb M13 labeled a particular type of cytoplasmic filament (Fig. 4F). In mitotic cells, these fibers disappeared and resulted in cytoplasmic dots. MAb 17F8 recognized a large cytoplasmic component similar to those in HEp-2 cells and stained the centrosomes (Fig. 4G, arrows). None of the antibodies reliably showed the nuclear BRCA1 staining anticipated from the other cell types. The absence of BRCA1 staining may be used as an indication of a lower concentration of BRCA1 in these nuclei and demonstrates the diversity of cross-reactivities of these antibodies.

Cell Cycle-related Nuclear Distribution of BRCA1. We asked whether the appearance of disparate BRCA1 distributions might be due to changes in the cell cycle as reported previously (4, 10, 45). This was tested by comparing the BRCA1 distribution pattern with cell size and the distribution of centromeres. Centromeres are present in singles very early during the cell cycle, aggregate in late G₁ and S phases, and can be found in doublets after the late S-phase replication of satellite DNA (46). Very early G₁-phase cells remain connected and show the Flemming body, and as shown in Fig. 4I, these daughter cells have no discrete BRCA1 domains. In contrast, the larger daughter cells have distinct BRCA1 accumulation and contain aggregated centromeres, suggestive of an S-phase cell. Late G₁-phase cells have started to spread out on the glass surface but retain the single centromere distribution and with it, dispersed BRCA1 distribution (Fig. 4J, top). Again, the larger cell pair in the same figure has BRCA1 accumulations and aggregated centromeres. Large cell pairs with double centromeres are considered cells in the G₂ phase of the cell cycle, and they largely have no BRCA1 accumulations (Fig. 4K). We have, however, found large cells with a considerable amount of highly aggregated BRCA1. Most of these cells may be polyploid, i.e., going through nuclear cycles of replication without cytokinesis. The changes in BRCA1 distribution correlate with cell size and centromere distribution and are therefore cell cycle dependent.

Correlation of BRCA1 Localization with Other Nuclear Structures. Because the nucleus appears to be highly compartmentalized, we tested whether BRCA1 accumulations might colocalize with any of the known nuclear compartments. Triple labeling was used to observe the relative location of BRCA1 with the SC35 and ND10 domains. We found that BRCA1 accumulations are largely excluded from the SC35 domains and ND10 (Fig. 5A; the yellow appearance of some of the juxtapositions is due to the fortuitous overlap of these domains). In this context, it is remarkable that ND10 is to a large extent situated adjacent to the SC35 domain, whereas only a small fraction of the BRCA1 accumulations abut any of these structures. It is likely that those that do are fortuitously abutting without any functional significance.

The nuclear domains labeled by anti-HP1 α antibodies (31) has been reported to have a cell cycle-associated distribution (47). When cells were double labeled for BRCA1 and HP1 α , we found three distribution patterns, as illustrated in adjacent cells in Fig. 5B. In the middle and smallest cell, sizable accumulations of HP1 α , but not BRCA1, are seen. The cell to the right shows several BRCA1 and HP1 α accumulations that are mostly separated. However, in the cell nucleus to the left, both antigens seem to be largely overlapping. This finding suggests that BRCA1 overlaps (colocalizes with) HP1 α only in a specific part of the cell cycle, most probably during S phase.

Because we had observed only very few cells with BRCA1 accumulations juxtaposed to ND10 and that these accumulations were usually rather large, we asked whether we could force more to this nuclear structure through the overexpression of BRCA1. When cells were transfected with the BRCA1 cDNA transcribed by the cytomegalovirus promoter and probed 16 h after transfection, we found all of the very large BRCA1 accumulations in close association with ND10 (Fig. 5C). These BRCA1 aggregations had a near circular outline, contrary to the more irregular outline of the endogenous large BRCA1 accumulations we occasionally found (Fig. 5D; the nucleus is outlined in blue by staining for DNA). High BRCA1 aggregations are therefore associated with a specific nuclear domain, ND10. Surprisingly, large amounts of endogenous, as well as overexpressed, BRCA1 accumulated only at a limited number of ND10 and was not equally divided among the ND10, as expected for a protein transported into the nucleus through randomly positioned pore complexes. Therefore, we tested several proteins (that had been reported to associate with ND10) as to whether they were present at only a limited number of ND10 and whether they might be attracting the excess BRCA1. The ubiquitin-specific protease, HAUSP, (48) was the only protein that showed a limited association with ND10 (Fig. 5E). However, its distribution and accumulation did not overlap with that of BRCA1 (data not shown).

Effect of Virus Infection on the BRCA1 Distribution. HAUSP has been characterized through its binding to the HSV1 immediate-early protein ICP0 (48). Because we could not find a direct binding of HAUSP with BRCA1, we asked whether the herpesvirus immediate-early protein ICP0, a transactivator that binds to HAUSP and disperses it from its high accumulations at some ND10, would also disperse the

Fig. 5. BRCA1 distribution in relation to other nuclear domains and after virus infection. **A**, triple labeling of HBL100 cells showing that BRCA1 staining does not colocalize with SC35 domains and ND10. **B**, double labeling of HBL100 cells showing that HP-1 may or may not colocalize with BRCA1. **C**, BRCA1-transfected HEp-2 cell showing that overexpressed BRCA1 localizes adjacent to a few ND10. **D**, HEp-2 cell showing high concentrations of endogenous BRCA1 at ND10. **E**, HEp-2 cell double labeled to show that HAUSP localizes adjacent to only a few ND10. **F**, HEp-2 cells 2 h.p.i. with wild-type HSV-1. Cells are double labeled for ICP0 to show which cells are infected and for BRCA1, demonstrating that BRCA1 is dispersed in infected cells. **G**, same as **A** but infected with the RING finger mutant FXE of HSV-1, indicating that infection with this mutant does not disperse BRCA1. **H**, uninfected HEp-2 cells showing the normal distribution of BRCA1 relative to ND10. **I**, HEp-2 cells 3 h.p.i. with Ad5 and stained for BRCA1 and SP100, indicating that SP100 has been distributed to short tracks and BRCA1 is located at many of these tracks. **J**, HEp-2 cells 8 h.p.i. with Ad5 and stained to show the single-stranded DNA binding protein DBP as an indicator where Ad5 replication begins and demonstrating that BRCA1 localizes adjacent to the replication domains. **K**, HEp-2 cells 12 h.p.i. with Ad5, double-labeled for DBP and BRCA1, indicating that BRCA1 localizes to the outer rim of the replication compartment (*upper right*) and is absent from the replication compartment at later stages of the replication cycle (*lower left*). **L**, HBL100 cells stressed for 1 h at 42°C and labeled for BRCA1. All BRCA1 accumulations have dispersed. Optical sections are $\sim 0.7 \mu\text{m}$ thick.

high accumulations of BRCA1 from ND10. We infected cells with wild-type HSV1 for 2 h. All infected cells could be identified by antibodies to the viral protein ICP0, and those so identified had only dispersed BRCA1 throughout the nucleus, whereas uninfected cells showed the expected BRCA1 accumulations (Fig. 5F). This finding shows only that wild-type HSV1 infection disperses BRCA1 accumulations but provides the assay with which to test whether mutations in ICP0 would retain BRCA1 accumulations. When cells were infected with an ICP0 mutant, FXE (where the RING finger region of ICP0 has been deleted), BRCA1 accumulations were retained (Fig. 5G). Thus, the dispersion of BRCA1 in S-phase nuclei by ICP0 represents a new effect of this viral transactivator on a cellular protein.

Ad5 also contains a protein (E4 ORF3) that modifies the location of HAUSP and ND10-associated proteins (39–41). We tested this virus early effect on BRCA1 distribution using the breast cancer cell line HBL100. In uninfected cells, BRCA1 and ND10 are largely positioned in separate domains (Fig. 5H). However, 3 h after infection, ND10 proteins were redistributed into many short tracks, and BRCA1 was now found in association with these tracks (Fig. 5I). Previously, we had shown by *in situ* hybridization that Ad5 replicates at sites where the viral single-stranded DNA protein, DBP, accumulates (41). At these later stages (8 h.p.i.), we found BRCA1 juxtaposed to replication domains (Fig. 5J). When these Ad5 replication domains expand, BRCA1 was recruited to these domains and surrounded them (Fig. 5K). When viral replication advanced further, as indicated by the accumulation of DBP throughout much of the nucleus, BRCA1 is no longer detected around these sites but only in those nuclear spaces where no viral accumulation is evident (left lower cell in Fig. 5K). Finding BRCA1 to be recruited to the outside of the viral replication domain where transcription of this virus takes place suggests that the virus makes use of this cellular protein in its transcriptional processes.

To test this hypothesis, we disturbed the global transcriptional processes through stress, which acts by shutting down normal transcription or processing and activating the transcription of the heat shock proteins (49–52). Such a global change may then either change BRCA1 distribution to: (a) a dispersed state in all cells; or (b) an accumulated state in all cells. When we treated HEP-2 cells for 1 h at 42°C, all BRCA1 accumulations were dispersed, with the BRCA1 distribution appearing as in cells in the G₁-phase of the cell cycle. BRCA1 distribution therefore changes in response to stress (heat shock) as well as to DNA-damaging agents (10, 53).

Discussion

Investigations of the molecular interactions of BRCA1 are progressing at several fronts, but knowledge of supramolecular events involving BRCA1 is largely absent. In this report, we have, therefore, begun to evaluate the distribution of BRCA1 at the cellular level during the cell cycle, determined its potential interactions at various nuclear domains, and have started to define its behavior in response to external stimuli, such as stress and viral infection. To embark on this work required antibodies that could be relied upon to visualize the location of BRCA1. Previously, BRCA1 had

been shown to localize to the cell membrane and was considered a secreted protein (12). This localization has since been shown to be due to the cross-reactivity of the C20 antibody to the EGF receptor (53, 54). We therefore produced a MAb (BR64) that recognizes the native antigen as well as BRCA1 expressed after transfection of various expression plasmids. When compared with other anti-BRCA1 MAbs, the MAb BR64 showed equivalent nuclear distribution but also reacted with a cytoplasmic component, the centrosome. The same reactivity was found for other BRCA1 MAbs and the polyclonal antibody C20. Although the centrosome reactivity of all these antibodies may be a cross-reactivity, the fact that the antibodies were made against quite different epitopes argues against this interpretation. We therefore consider that this result is suggestive of BRCA1 binding to this cellular domain so intimately involved in mitotic events. Furthermore, our use of BR64 hybridoma supernatant excludes the possibility of a contaminating mouse autoantibody. The reaction of C-20 with the Flemming body, however, may be such an autoantibody present in rabbits. The least useful MAb for our analyses was 17F8, because it cross-reacted with a number of cytoplasmic granules. Furthermore, because of the thickness of the optical section (~0.7 μ m), these granules overlaid the nuclear domain and did not allow for an unbiased determination of the nuclear distribution of BRCA1. The cross-reactivity of M13 with cytoplasmic filaments made this antibody useful only for cells without these filaments. We had observed, however, that even HEP-2 cells in mitosis had the cytoplasmic dot characteristic of depolymerized intermediate filaments. The faint cytoplasmic staining in HEP-2 cells may therefore be due to a low level of these filaments. The general conclusions of the comparison of the different BRCA1 antibodies is that: (a) they collectively validate the presence of BRCA1 in the nucleus; and (b) they can be used to evaluate the redistribution of BRCA1 induced by internal physiological changes and externally induced effects, but only in cells where the cross-reactive proteins are absent.

For all antibodies, we had observed two distribution patterns for BRCA1, dispersed and aggregated. That smaller cells had only dispersed BRCA1 suggested a cell cycle-related event. A general interruption of the cell cycle is possible through the application of stress in the form of heat shock. Cellular transcription and splicing is reduced and shifted to heat shock protein transcription. Under these conditions, BRCA1 becomes dispersed from its domains, similar to other proteins resident in other domains. Whether this phenomenon can be attributed to a change in transcription or to the subsequent cell cycle retardation is not clear, but it presents a new single-cell assay of an as-yet-to-be defined BRCA1 function.

There are no precise cell cycle markers that can be used in a single-cell assay such as microscopy, particularly because the BRCA1 epitopes seem to be sensitive to the acid treatment necessary to expose the S-phase indicator bromodeoxyuridine.⁴ However, He and Brinkley (46) showed that cen-

⁴ G. Maul, unpublished results.

centromeres behave quite predictably during the cell cycle. The dispersion of the centromeres after mitosis lasts into later parts of G₁ and was correlated with dispersed states of BRCA1. The centromeres aggregated later, and the numbers that can be counted are far below those expected for the number of chromosomes present. This stage corresponds, according to He and Brinkley (46), to the S-phase and is clearly correlated with the presence of aggregated BRCA1. At the end of the cell cycle, cells are rather large, and the centromeres are present as pairs and are not highly clustered. The distribution pattern of BRCA1 in large cells is less clear, but the bulk of those observed (which had paired centromeres) also had few or no sites of aggregated BRCA1. From these observations, it is clear that BRCA1 changes its distribution during the cell cycle and that aggregation is predominantly present during the S-phase of the cell cycle, with a more precise definition of this phenomenon not presently possible. Arising from these observations is the question of whether the areas of accumulation define the sites of active BRCA1, or whether, alternatively, BRCA1 may act in the "dispersed" mode with the "aggregated" state being sites of storage for BRCA1 (segregation).

The nucleus is partitioned into domains of various activities. Not only do specific chromosomal territories exist (55), but so do various extrachromosomal domains to which specific functions are attributable and which can be delineated with the respective antibodies. We did not find any domain that consistently colocalized with BRCA1. BRCA1 accumulations definitely reside outside of the SC35 domain and the ND10. However, BRCA1 accumulations overlap HP1 α during a stage of S phase. PIKA represent domains of highly aggregated HP1 α , a protein that is normally associated with heterochromatin (47). HP1 α has also been shown to change its aggregation pattern during the S-phase of the cell cycle (47). Contrary to BRCA1, however, it starts in a highly aggregated, BRCA1-sized domain, during G₁. The temporary association of the two proteins in the same nuclear domain does not necessarily signify direct interaction, a conclusion supported by a two-hybrid assay in which no interaction could be found.⁴ Other proteins may be intermediaries; however, these two proteins are the only ones presently showing cell cycle-dependent colocalization.

The accumulation of a protein may be viewed as indicative of: (a) functioning at this site; (b) as segregation with the implication of removing the protein from functioning; or (c) storing excess protein as a means to regulate the precise amount of protein in a delicate balance. This balance may change during the cell cycle. Under these assumptions, we may either conclude that BRCA1 has specific nuclear sites of high activity during S phase, or its concentration throughout the nucleus is lowered by segregation during this part of the cell cycle. The possibility that the cell has the capability to segregate endogenous BRCA1 is supported by the finding of high concentrations close to ND10 and the accumulation of BRCA1 at these sites when overexpressed. We may be witnessing segregation of BRCA1 into a nuclear dump or nuclear depot (56).

Viruses have often been instrumental in the elucidation of cellular functions. Using two DNA viruses we could demon-

strate that they modify BRCA1 distribution quite differently and provide a single-cell assay to test this perturbation. The dispersion of BRCA1 by HSV1 may be due to the interruption of the cell cycle as HSV1 blocks S phase (57). However, we were able to define the immediate-early HSV1 *IE1* gene as an essential gene for BRCA1 dispersion. Its potential interaction with a BRCA1 pathway may lay at the center of the inability of cells to grow when ICP0 is constitutively expressed.⁴

Ad5 has a quite different effect on BRCA1. BRCA1 accumulates at and surrounds some of the replication sites during the viral replication. Later, after transcription and replication cease late in the replication cycle, BRCA1 is no longer present around the viral replication domain as indicated by staining against DBP. The outer fringe of the replication site represents viral single-stranded DNA that is being transcribed, whereas the center contains double-stranded Ad5 DNA (58). The presence of BRCA1 at the outer region of Ad5 suggests that it may be used in viral transcription. Alternatively, because this outer region is also where decatenation of the viral DNA takes place, BRCA1 accumulation in this area may suggest a role in this process, a role supported by the observation that BRCA1 may be involved in the cross-over mechanism during pachyteen of meiosis (6).

This investigation establishes that there is a cell cycle-related change in the distribution of BRCA1 in the nucleus and that another protein, HP1, involved in transcriptionally silencing chromatin, colocalizes during part of BRCA1 accumulation/segregation. We found that DNA viruses change the distribution of BRCA1 substantially and, in the case of Ad5, temporarily recruit this protein into an area of high transcriptional activity.

Materials and Methods

Cell Culture. All cells were maintained at 37°C and 5% CO₂. MCF7 cells (ATCC HTB 22) and HBL-100 (ATCC HTB 124) cells were grown in high glucose DMEM containing 10% FBS and 0.1 mM nonessential amino acids. MDA-MB-468 (ATCC HTB 132) cells were grown in a 1:1 mix of high glucose DMEM and Ham's F-12 with 10% FBS. Human WI38 fibroblasts (ATCC CCL 75) and the epithelial cell line HEP-2 (ATCC CCL 23) were maintained in MEM supplemented with 10% FCS and antibiotics.

³²PO₄ Labeling of MDA-MB-468 Cells. MDA-MB-468 cells were rinsed twice with warm, phosphate-free DMEM (hi glucose) medium and then incubated in phosphate-free medium containing 5% dialyzed FBS for 2 h. The cells were then placed in phosphate-free medium containing 5% dialyzed FBS and ³²PO₄ (100 μ Ci/ml; NEN) and incubated for an additional 2 h. Cells were harvested in RIPA buffer containing 50 mM NaF and protease inhibitors [20 mM HEPES (pH 7.4), 140 mM NaCl, 1% Triton X-100, 1% deoxycholate, 0.1% SDS, 1 mM EDTA, 1 mM phenylmethylsulfonyl fluoride, 2 μ g/ml leupeptin, 0.04 TI units/ml aprotinin, and 2 μ g/ml pepstatin].

MAb Production. A synthetic gene of the BRCA1-RF domain (amino acids 1–100) was made from overlapping oligonucleotides whose codon usage had been optimized for expression in *E. coli* and *Saccharomyces cerevisiae* (5, 59). Double-stranded DNA was generated by the PCR. This BRCA1 partial cDNA was fused downstream of the six His residues of the vector pQE-30 (Qiagen, Inc.). The His-tagged protein was purified from *E. coli* over a nickel-agarose column as described previously (20). Fifty μ g of recombinant 6XHis-BRCA1 fusion protein, in 50 μ l PBS, was emulsified in complete Freund adjuvant and injected s.c. into BALB/c mice, followed by three boosts in incomplete Freund adjuvant. The fourth boost was given i.v., and the splenocytes were fused 3 days later with the mouse nonimmunoglobulin-secreting cell line P3X63Ag8.SP2/0. Hybridomas were selected by testing supernatants by ELISA on recombinant 6XHis-BRCA1.

Each clone was subcloned following standard procedures. All resulting MAbs were of IgG1, kappa.

Immunoprecipitations. Immunoprecipitation of samples with polyclonal Abs was performed with protein A-Sepharose (Pharmacia). The MAb BR64 was precipitated with protein G-Sepharose (Pharmacia). Immunoprecipitations were carried out by incubating the antibody with protein extract or *in vitro*-produced protein in 1 ml of RIPA buffer for 2 h at 4°C. The protein G (or A) Sepharose resin was then added, and the reaction incubated an additional 30–45 min at 4°C with continual mixing. The bound proteins were washed in RIPA buffer five times, released from the Sepharose resin with SDS-PAGE loading dye, and separated by SDS-PAGE. Visualization of bound protein was performed by autoradiography.

Western Blot Analysis. Proteins were separated by SDS-PAGE and transferred to PVDF membrane (Millipore) via standard methods. In Fig. 2B, the membrane was blocked in Tris-buffered saline containing 0.1% Tween-20 (TBST) and 5% fish gelatin (Forma Scientific). The MAb BR64 ascites fluid was diluted 1:1000 in the block buffer and incubated with the membrane for 2 h at room temperature with gentle shaking. After washing the membrane five times with TBST (10 min each), the blot was incubated with secondary antibody conjugated to horseradish peroxidase (goat anti-mouse IgG-HRP; Bio-Rad) at 1:5000 dilution for 30 min. The membrane was washed five times further and developed with Super Signal (Pierce). In Fig. 2C, the membrane was blocked for 1 h in Tris-buffered saline containing 0.2% Tween-20 (TBST2) and 5% dry milk. The MAb BR64 ascites fluid was diluted to 0.5 µg/ml (TBST2 plus 1% BSA) and incubated with the membrane for 1 h at room temperature with gentle shaking. After washing the membrane three times with TBST2 (10 min each), the blot was incubated with secondary antibody conjugated to alkaline phosphatase (alkaline phosphatase anti-mouse IgG; Promega) at 1:7500 dilution (TBST2 plus 1% BSA) for 45 min. The membrane was washed three times further and developed using 5-bromo-4-chloro-3-indolyl phosphate/nitroblue tetrazolium color development substrates (Promega).

Transfections and *in Vitro* Transcription/Translation. Cells were transiently transfected by calcium phosphate precipitation (60). The Promega TNT kit was used as described by the manufacturer to produce ³⁵S-labeled protein. Proteins were used for analysis without further purification. Plasmid constructs bearing BRCA1 and BRCA1-Δ11 were kind gifts of F. Calzone (Amgen, Inc., Thousand Oaks, CA). The RPT-1 cDNA was a kind gift of H. Cantor (Dana-Farber Cancer Institute, Boston, MA) (44).

Antibodies Used for Immunofluorescence. Antibodies used for the detection of BRCA1 were: M13, a MAb kindly provided by R. Scully (Dana-Farber Cancer Institute, Boston, MA) (61); 17F8, a MAb kindly provided by W. H. Lee (Center for Molecular Medicine, University of Texas Health Science Center, San Antonio, TX) (11); and C20, a rabbit polyclonal antibody that was purchased from Santa Cruz Biotechnologies (Palo Alto, CA).

ND10 were visualized using MAb 1150, which recognizes Sp100 (62). The human antibody 1745, which recognizes Sp100 and PML, was used in triple-labeling experiments (62). MAb anti-SC35 (25) was used to label the SC35 domain. MAbs against HAUSP and ICP0 were provided by R. Everett (Medical Research Council, Glasgow, UK) (48). Isotype-matched MAbs of unrelated specificity served as controls. Rabbit anti-HP1α antibodies were obtained from W. Earnshaw (University of Edinburgh, Edinburgh, UK) (31).

Immunohistochemistry. Cells were fixed at room temperature for 15 min with freshly prepared 1% paraformaldehyde in PBS, washed with PBS, and permeabilized for 20 min on ice with 0.2% (v/v) Triton X-100 (Sigma Chemical Co.) in PBS. Antigen localization was determined after incubation of permeabilized cells with rabbit antiserum, MAb, or human antiserum diluted in PBS for 1 h at room temperature. Avidin-fluorescein or avidin-Texas Red was complexed with primary antibodies through biotinylated secondary antibodies (Vector Laboratories). Cells were double- or triple-labeled with the respective second antibodies conjugated with FITC, Texas Red, or Cy-5 using biotin-avidin enhancement and FITC for structures with the lowest staining intensity. Cells were then stained for DNA with 0.5 µg/ml of bis-benzimide (Hoechst 33258; Sigma) in PBS and mounted with Fluoromount G (Fisher Scientific). Cells were analyzed using a Leica confocal scanning microscope. The two channels were recorded simultaneously when no cross-talk was detectable. In the case of intense

FITC-labeling, sequential images were acquired with more restrictive filters to prevent possible breakthrough of the FITC signal into the red channel. Both acquisition modes gave the same results. Leica image enhancement software was used in balancing signal strength. Because of the variability of the infectious cycle progression in any given culture, the most prevalent and representative images were photographed and presented as a limited number of nuclear images to retain high magnification. At least 500 cells were studied in each sample.

Virus Infection. Two days after plating, HEP-2 cells were infected with HSV-1 17+ at 2 plaque-forming units/cell, resulting in 95% infected cells as determined by staining for ICP0 antibodies at 5 h.p.i. Cells were fixed at different intervals after infection and assayed with different antibodies as described (34). Ad5 infection was carried out as described (41), and cells were fixed at various times after infection.

Acknowledgments

We thank Dr. F. Calzone for the BRCA1 and BRCA1-Δ11 cDNAs, Dr. J. Frey for anti-Sp100 antibodies, Dr. R. Scully for the M13 antibody, Dr. Wen-Hwa Lee for the 17F8 antibody, Dr. R. Everett for the wild-type herpes virus and its ICP0 mutant FXE and ICP0 and HAUSP antibodies, Dr. R. Shiekhattar for performing the BRCA1 Western analyses and providing the blocking peptide for BR64, and Qin Wu Lin for excellent technical assistance in the microscopy facility. We thank Jing Wang and Marin Feldman for excellent technical assistance. The use of the Wistar Institute Cancer Center vector facility for the preparation of Ad5 stock, the monoclonal antibody facility for producing the BRCA1 reactive hybridomas, and the DNA sequencing facility for confirmation of all BRCA1 mutants are acknowledged.
